The patient was a 12-year-old boy who presented with shortness of breath on minimal activity and was diagnosed with multiple arteriovenous (AV) malformations in the left lung. Figure 1 shows an AV malformation in the left lower lobe. Figure 2 shows the same malformation after percutaneous coil embolization. Multiple malformations were embolized, and at the end of the procedure (Figure 3), the patient’s $PaO_2$ had risen from 50 to 66 mm Hg.
Percutaneous Coil Embolization of Multiple Arteriovenous Malformations in Left Lung Causing Persistent Hypoxia
