Mechanism of Recurrent/Persistent Ischemic/Functional Mitral Regurgitation in the Chronic Phase After Surgical Annuloplasty

Importance of Augmented Posterior Leaflet Tethering

Levine, MD; Ryuizo Sakata, MD; Chuwa Tei, MD

Background—Surgical annuloplasty can potentially hoist the posterior annulus anteriorly, exaggerate posterior leaflet (PML) tethering, and lead to recurrent ischemic/functional mitral regurgitation (MR). Characteristics of leaflet configurations in late postoperative MR were investigated.

Methods and Results—In 30 patients with surgical annuloplasty for ischemic MR and 20 controls, the anterior leaflet (AML) and PML tethering angles relative to the line connecting annuli, posterior and apical displacement of the coaptation and the MR grade were measured by echocardiography before, early after, and late after surgery. Early after surgery, grade of MR and AML tethering generally decreased (P<0.01), whereas PML tethering significantly worsened (P<0.01). Nine of the 30 patients showed recurrent/persistent MR late after surgery. Compared with patients without late MR, those with the MR showed similar reduction in the annular area, significant re-increase in posterior displacement of the coaptation, and progressive worsening in PML tethering (P<0.05) late after surgery in comparison to the early phase. Both preoperative MR and late postoperative MR were significantly correlated with all tethering variables in univariate analysis. Although apical displacement of the coaptation was the primary determinant of preoperative MR (r²=0.60, P<0.0001), increased PML tethering was the primary determinant of late MR (r²=0.75, P<0.0001).

Conclusions—Whereas both leaflets tethering is related to preoperative ischemic MR, both leaflets tethering but with predominant contribution from augmented and progressive PML tethering is related to recurrent/persistent ischemic/functional MR late after surgical annuloplasty. (Circulation. 2006;114[suppl 1]:I-529–I-534.)

Key Words: coronary disease mitral valve valvuloplasty

Although surgical annuloplasty for ischemic/functional mitral regurgitation (MR) is effective,¹–³ a considerable number of patients show recurrent/persistent MR,³–⁶ which adversely affects mortality⁷ without established mechanism.

Mitral leaflet tethering by the outward displacement of papillary muscles (PM) caused by left ventricular (LV) remodeling is the basic mechanism of ischemic MR.⁸–¹⁴ Surgical annuloplasty, which may hoist the posterior annulus anteriorly without displacing the anterior annulus fixed at the aortic root, can potentially and specifically augment posterior leaflet (PML) tethering by increasing the distance between the PM tip and posterior annulus without affecting anterior leaflet (AML) tethering (Figure 1).¹⁵ We hypothesized that ischemic MR before surgical annuloplasty is related to both leaflets tethering, and that the MR afterward is also related to both leaflets tethering but with PML predominance. This hypothesis has been tested for persistent ischemic MR early after surgery.¹⁶ However, this has not been tested for recurrent/persistent MR in the chronic phase after surgery. Therefore, the purpose was to investigate leaflet configurations in patients with ischemic/functional MR before and late after surgical annuloplasty, and to clarify the characteristics of leaflet configurations responsible for recurrent/persistent ischemic MR.

Methods

Subjects

Subjects consisted of 51 consecutive patients who underwent surgical annuloplasty for ischemic/functional MR in our hospital and 20...
Mitral leaflet configuration was quantified in the mid-systolic parasternal long-axis view (Figure 2). AML and PML tethering was measured as the angles $\alpha_1$ and $\alpha_2$, respectively. AML tethering from secondary chordae was measured as the bending angle $\beta$ between tangent lines of proximal and distal AML. $\alpha_1$ significantly decreased early after surgery ($P<0.01$) and kept constant afterward in both groups. The $\alpha_2$ significantly decreased early after surgery in both groups ($P<0.05$). Whereas patients without late MR had further reduction in LVESV late after surgery ($P<0.05$), those with the MR had re-increase but without statistical significance. LV EF significantly improved early after surgery only in patients without late MR ($P<0.05$). LVEF kept constant afterward in both groups. The mitral annulus area significantly decreased early after surgery ($P<0.05$) and kept constant afterward in both groups.

Results

Incidence of Early and Late Postoperative Ischemic MR

Early after the surgery, severity of MR significantly decreased (VC width, $3.7 \pm 1.6$ versus $0.2 \pm 0.8$ mm; $P<0.001$) and 2 patients had persistent MR. Late after the surgery, the MR significantly re-increased (0.2 $\pm 0.8$ to 1.3 $\pm 2.0$ mm; $P<0.01$), resulting with 2 patients with early postoperative MR and significant MR, and an additional 7 in whom recurrent MR developed. These 9 patients comprised the group with late postoperative MR and the remaining 21 comprised the group without it (Table 1).

Changes in LV Volume, Mitral Leaflet Configuration, and MR in Patients Without and With Late Postoperative MR (Table 2)

Severity of MR significantly decreased early after surgery in both groups ($P<0.01$). Although patients without late MR did not show re-increase in the MR late after surgery, those with it had significant re-increase ($P<0.01$). The LVESV significantly decreased in both groups early after the surgery ($P<0.05$). Whereas patients without late MR had further reduction in LVESV late after surgery ($P<0.05$), those with the MR had re-increase but without statistical significance. LV EF significantly improved early after surgery only in patients without late MR ($P<0.05$). LVEF kept constant afterward in both groups. The mitral annulus area significantly decreased early after surgery ($P<0.05$) and kept constant afterward in both groups.

D$_1$ significantly decreased early after surgery in both groups ($P<0.05$). Whereas D$_1$ kept constant afterward in patients without late MR, it significantly re-increased in those with the MR ($P<0.05$). D$_2$ significantly decreased early after surgery ($P<0.01$) and kept constant afterward in both groups. The $\alpha_1$ significantly decreased early after surgery in both groups ($P<0.05$). Although it kept constant afterward in patients without late MR, it re-increased in those with the MR but without statistical significance. The $\alpha_2$ significantly increased early after surgery in both groups ($P<0.01$). Patients without late MR did not show progressive increase in $\alpha_2$ afterward, but those with it showed significant progression.
The $\beta$ significantly increased early after surgery only in patients without late MR. Whereas it kept constant afterward in patients without late MR, it significantly decreased in those with the MR ($P<0.05$).

Preoperatively, increase in $\alpha_1$ compared with mean normal value was comparable with that in $\alpha_2$ in both groups (no late MR, plus 22±6 versus 24±9 degree, not significant; late MR, plus 22±3 versus 24±7 degree, not significant). Therefore, preoperative tethering was similar between AML and PML. However, early after surgery, increase in $\alpha_1$ compared with mean normal value was significantly smaller than that in $\alpha_2$ in both groups (no late MR, plus 16±3 versus 56±5 degree, $P<0.01$; late MR, plus 17±6 versus 57±15 degree, $P<0.01$). Therefore, early postoperative leaflet tethering was asymmetric with PML predominance, which showed significant progression only in patients with late MR (57±15 to 81±10 degree, $P<0.01$).

### Determinants of Preoperative and Late Postoperative MR (Table 3)

Multiple regression analysis identified primary independent contribution from increased $d_2$ for the preoperative VC width along with increased $\alpha_1$ and $d_1$, suggesting that combination of both leaflets tethering was the main determinant of preoperative MR.

Multiple regression analysis identified primary contribution from increased $\alpha_2$ for the late postoperative VC width along with decreased $\beta$ and increased $d_1$, suggesting that combination of both leaflets tethering but with predominant contribution from augmented PML tethering was the main determinant of the late MR (Figure 3).

Figure 4 demonstrates representative patients. Compared with the normal subject in the left upper panel, the patient with ischemic MR without annuloplasty in the right upper panel has similarly increased AML and PML tethering. The patient without late postoperative MR in the middle panels had predominant PML tethering. The patient in the lower panels with late MR had more advanced PML tethering and LV remodeling.

### Change in LV Volume and Leaflet Tethering Late After Surgery

Reduction in LVESV late after surgery relative to preoperative phase was significantly correlated with less leaflet...
tethering ($\Delta$MR jet width: $r^2=0.57$, $P<0.0001$; $\Delta\alpha_1$: $r^2=0.18$, $P<0.05$; $\Delta\alpha_2$: $r^2=0.46$, $P<0.0001$; $\Delta d_1$/body surface area [BSA]; $r^2=0.29$, $P<0.005$; $\Delta d_1$/BSA: $r^2=0.15$, $P<0.05$; $\Delta\beta$: $r^2=0.24$, $P<0.01$). Progressive increase in LVESV from early to late postoperative phase was significantly correlated with progressive leaflet tethering ($\Delta$MR jet width: $r^2=0.47$, $P<0.0001$; $\Delta\alpha_1$: $r^2=0.16$, $P<0.05$; $\Delta\alpha_2$: $r^2=0.50$, $P<0.0001$; $\Delta d_1$/BSA: $r^2=0.38$, $P<0.005$; $\Delta d_1$/BSA: $r^2=0.08$, n.s.; $\Delta\beta$: $r^2=0.34$, $P=0.001$).

Recurrent ischemic MR despite surgical annuloplasty is related to leaflet tethering by progressive LV remodeling.6 Green et al has observed restricted PML after surgical annuloplasty,15 which was related to early postoperative persistent ischemic MR.16 Results of this study are consistent with these and further revealed importance of augmented PML tethering for the recurrent/persistent ischemic MR in the chronic phase after surgical ring annuloplasty.

Clinical Implications

Although mitral annuloplasty may not directly relieve ventricular tethering, it is effective to repair ischemic/functional MR by reducing antero-posterior annular dimension to re-

### Discussion

**Different Leaflet Configurations in Preoperative and Postoperative Ischemic/Functional MR**

This study has demonstrated that ischemic MR without surgical ring annuloplasty is associated with approximately symmetrical AML and PML tethering. Early after the surgery, only PML tethering significantly increased in both patients without and with late MR. The PML tethering showed progressive worsening late after surgery in patients with late MR. Therefore, AML and PML tethering is asymmetric with PML predominance in patients with surgical annuloplasty and the asymmetry was progressive only in those with late recurrent/persistent MR. Posterior displacement of the coaptation after annuloplasty in patients with late MR can be explained as a result of restricted PML. This augmented PML tethering contributed to recurrent/persistent ischemic MR late after ring annuloplasty.

### Relation to Previous Studies

In chronic phase after surgical ring annuloplasty.

AML indicates anterior leaflet; BSA, body surface area; D/L, short-to-long axis dimension ratio; EF, ejection fraction; EDV, end-diastolic volume; ESV, end-systolic volume; LV, left ventricular; MAA, mitral annular area; MR, mitral regurgitation; PML, posterior leaflet.
store reduced coaptation by tethering. However, PML tethering was significantly increased afterward even in patients without postoperative MR. Therefore, mitral annuloplasty reduces antero-posterior annular diameter at the expense of augmented PML tethering. When the former effect is predominant, MR can be eliminated by ring annuloplasty. However, when the former is not predominant, recurrent MR may develop. Results of this study suggest need for aggressive undersized annuloplasty, because longer AML than antero-posterior annular diameter is required in the presence of restricted PML. At the same time, more posterior location of the coaptation than posterior annulus and significant bending of AML by tethering from basal chordae in patients with late MR suggest that considerably longer AML than annular diameter is required to prevent leakage. In addition, reduction in LVESV after the surgery was associated with less tethering. These also encourage interventions addressing ventricular tethering, such as LV plasty, chordal elongation or cutting, PM alignment, leaflet elongation, and others. Further, interventions addressing PML tethering are also encouraged.

**Limitations**

Multiple patients were excluded because of the lack of serial echocardiography; therefore, the incidence of recurrent/persistent MR may not be accurate. Blinded measure to surgical outcome was not performed because of black and white echo images and color images are on the same set of postoperative images. All patients with serial echocardiography after surgical annuloplasty for ischemic/functional MR were investi-
gated to address characteristics of recurrent/persistent MR with heterogeneous etiology and procedure. However, the small number of studied patients requires further investigations to address specific issues such as recurrent/persistent MR after isolated annuloplasty, effects of rigid and flexible ring annuloplasty with or without aggressive undersizing, and effects of different types of LV plasty in patients with specific etiologies such as different location of myocardial infarction or nonischemic LV dysfunction. Nevertheless, the purpose of this study was achieved by demonstrating significant contribution of augmented and progressive PML tethering for the recurrent/persistent ischemic MR in the chronic phase after surgical ring annuloplasty.
