Reversal of Cardiac Hypertrophy and Fibrosis From Pressure Overload by Tetrahydrobiopterin
Efficacy of Recoupling Nitric Oxide Synthase as a Therapeutic Strategy

Background—Sustained pressure overload induces pathological cardiac hypertrophy and dysfunction. Oxidative stress linked to nitric oxide synthase (NOS) uncoupling may play an important role. We tested whether tetrahydrobiopterin (BH4) can recouple NOS and reverse preestablished advanced hypertrophy, fibrosis, and dysfunction.

Methods and Results—C57/B6 mice underwent transverse aortic constriction for 4 weeks, increasing cardiac mass (190%) and diastolic dimension (144%), lowering ejection fraction (46%), and triggering NOS uncoupling and oxidative stress. Oral BH4 was then administered for 5 more weeks of pressure overload. Without reducing loading, BH4 reversed hypertrophy and fibrosis, recoupled endothelial NOS, lowered oxidant stress, and improved chamber and myocyte function, whereas untreated hearts worsened. If BH4 was started at the onset of pressure overload, it did not suppress hypertrophy over the first week when NOS activity remained preserved even in untreated transverse aortic constriction hearts. However, BH4 stopped subsequent remodeling when NOS activity was otherwise declining. A broad antioxidant, Tempol, also reduced oxidant stress yet did not recouple NOS or reverse worsened hypertrophy/fibrosis from sustained transverse aortic constriction. Microarray analysis revealed very different gene expression profiles for both treatments. BH4 did not enhance net protein kinase G activity. Finally, transgenic mice with enhanced BH4 synthesis confined to endothelial cells were unprotected against pressure overload, indicating that exogenous BH4 targeted myocytes and fibroblasts.

Conclusions—NOS recoupling by exogenous BH4 ameliorates preexisting advanced cardiac hypertrophy/fibrosis and is more effective than a less targeted antioxidant approach (Tempol). These data highlight the importance of myocyte NOS uncoupling in hypertrophic heart disease and support BH4 as a potential new approach to treat this disorder. (Circulation. 2008;117:2626-2636.)

Key Words: antioxidants ■ heart failure ■ hypertrophy ■ nitric oxide synthase ■ reactive oxygen species ■ remodeling ■ therapeutics

Sustained pressure overload stimulates pathological cardiac hypertrophy and dysfunction, and reversing such maladaptations has emerged as an important therapeutic goal. A prominent pathway is activation of reactive oxygen species (ROS), which contributes to chamber remodeling and contractile failure. Although treatment with ROS scavengers has not been very effective to date, suppression of key ROS generators in the myocardium may prove more so. Myocardial ROS sources include xanthine and NADPH oxidases, mitochondrial electron transport, and nitric oxide synthase (NOS), and among these, some recent evidence suggests that NOS may be particularly important to more advanced dilative disease. NOS behaves somewhat like Jekyll and Hyde, generating NO to provide antioxidant and antihypertrophic effects yet contributing to cardiovascular pathobiology if it becomes functionally uncoupled. This occurs if the normal flow of electrons from NADPH in the reductase domain to heme in the amino-terminus oxidase domain is disturbed.
limiting NO synthesis and favoring superoxide generation by
dissociation of the ferrous-dioxyn complex.6-7 Endothelial
NOS (eNOS) uncoupling has been documented in hyperpres-
sion,8 diabetes,9 and atherosclerosis10 and may have a promi-
ient role in cardiac hypertrophic remodeling.11

**Clinical Perspective p 2636**

A major cause of eNOS uncoupling is depletion and/or
oxidation of tetrahydrobiopterin (BH4).12,13 BH4 is an obli-
gate cofactor for the 3 aromatic amino acid hydroxylases,14
and insufficiency of phenylalanine hydroxylase causesphe-
nylketonuria, a genetic disorder characterized by progressive
mental retardation. Affected individuals must follow a
phenylalanine-restricted diet, and BH4 replacement therapy
can reduce phenylalanine levels and appears to be useful for
treating a substantial number of these patients.15 BH4 also is
required for normal NOS function (reviewed elsewhere16). It
is synthesized de novo from guanosine triphosphate (GTP),17
with the rate-limiting enzyme being GTP cyclohydrolase-1
(GCH). Models in which GCH is genetically enhanced in
endothelial cells show suppressed diabetic and atherosclerotic
vasculopathy.9,12 Effective BH4 levels also depend on redox
state because the oxidized form of BH4 (BH2) does not serve
as an NOS cofactor. BH4 levels decline in pressure-overload
hypertrophy in conjunction with NOS uncoupling,11 but
whether BH4 supplementation can treat already established
advanced disease and whether this involves targeted eNOS
recoupling are unknown. Here, we demonstrate that exoge-
nous BH4 can indeed recouple NOS and reverse advanced
hypertrophy/dilation more effectively than a less specific
antioxidant strategy.

**Methods**

**General Experimental Model**

Seventy-six male mice (C57BL/6; age, 8 to 9 weeks; weight, 22 to
24 g) underwent transverse aortic constriction (TAC) as previously
described.15,18 Animals were screened by echocardiography at 4
weeks for hypertrophy and an ejection fraction (EF) <70% (chamber
dilation). Of these animals, 10 were killed for tissue analysis, and the
remaining were randomized to receive BH4, Tempol, or vehicle
treatment during 5 more weeks of TAC. At 9 weeks, subsets of these
animals were randomly selected and used for molecular, cellular,
and enzymatic assays; histopathology; or in vivo function analysis. BH4
animals were randomly selected and used for molecular, cellular, and
treatment during 5 more weeks of TAC. At 9 weeks, subsets of these
animals, 10 were killed for tissue analysis, and the
remaining were randomized to receive BH4, Tempol, or vehicle
treatment during 5 more weeks of TAC. At 9 weeks, subsets of these
animals were randomly selected and used for molecular, cellular,
and enzymatic assays; histopathology; or in vivo function analysis. BH4
animals were randomly selected and used for molecular, cellular, and
in vivo function analysis. BH4 (200 mg·kg⁻¹·d⁻¹; Schircks Laboratories, Jona, Switzerland) or
vehicle was mixed in soft diet, and Tempol (10 mg/g food; 1.67
g·kg⁻¹·d⁻¹; vehicle was premixed in solid food logs (Bio-
Serv, Frenchtown, NJ). All animal protocols were approved by the
Animal Care and Use Committee of Johns Hopkins University.

**Endothelial GTP Cyclohydrolase Transgene Overexpression**

GTP cyclohydrolase transgenic (GCH-Tg) mice (n=24) and non-
transgenic control littermates (n=16) were subjected to 12 weeks of
TAC. Age-matched sham controls also were generated. Serial
echocardiography and final sacrifice tissue analysis were performed.

**Cardiac Function and Geometry**

In vivo cardiac geometry and function was serially assessed by
transthoracic echocardiography (Acuson Sequoia C256, 13-MHz
transducer, Siemens Medical Systems, Malvern, Pa) in conscious
mice. M-mode left ventricular (LV) end-systolic and end-diastolic
dimensions were averaged from 3 to 5 beats, and data were analyzed
by investigators blinded to heart condition as described.11 In a subset
of mice, LV function was assessed by pressure-volume relations
(SPR 839, Millar Instruments Inc, Houston, Tex) in anesthetized
animals as described.11

**Histology**

Myocardium was fixed in 10% formalin and stained with hemato-
xylin and eosin, periodic acid-Schiff methylene silver, or Masson’s
tricrome to determine myocyte cross-sectional diameter (mean, 40
cells from 3 slices in 4 to 5 different hearts) and interstitial fibrosis.
Fibrosis was scored 0 to 3 by a pathologist blinded to heart condition.

**Whole-Cell Myocyte Shortening and Calcium Transients**

Adult myocytes were isolated from left ventricles, and cell shorten-
ing and calcium transient changes (Indo-1-AM) were determined by
fluorescence microscopy (Diaphot 200, Nikon, Inc, Melville, NY)
equipped with image/analysis (IonOptix, MyoCam, Milton, Mass) as
described.20 Data were assessed in control and 9-week TAC hearts
with or without BH4 treatment.

**eNOS Monomer-to-Dimer Ratio and Activity**

Cold SDS-PAGE Western blot analysis was performed in self-made
7% to 4% SDS-Tris gels run overnight on ice and then transferred for
3 hours to nitrocellulose membranes. Primary eNOS antibody
(1:350, Santa Cruz Technology, Inc, Santa Cruz, Calif) was detected by
enhanced chemiluminescence (Pierce, Rockford, Ill). NOS activ-
ity was measured from myocardial homogenates (80 μg protein) by
cGTP-dependent arginine to citrulline conversion (Stratagene, La Jolla, Calif).11

**cGMP-Dependent Protein Kinase Activity**

cGMP-dependent protein kinase (PKG)-1 activity was assayed from
whole-heart protein lysates by ELISA (CycLex-PKG assay kit,
MBL, Woburn, Mass) and immunoblot for PKG-phosphorylated
vasodilator-stimulated protein with a monoclonal antibody to PS239
vasodilator-stimulated protein (Alexis, Lausen, Switzerland) at
1:1000 dilution.20

**Superoxide Determination**

Myocardial superoxide was measured by dihydroethidine fluorescent
microtopography and lucigenin-enhanced chemiluminescence. Fresh-frozen
8-μm LV slices were incubated for 1 hour at 37°C with
dihydroethidine (2 μmol/L, Invitrogen, Carlsbad, Calif) and fluores-
cence imaged as described.11 For lucigenin analysis, fresh-frozen
myocardium was homogenized and centrifuged at 4000 RPM for 30
seconds; lucigenin (5 μmol/L) and NADPH (100 μmol/L) were
added to the supernatant; and chemiluminescence was measured by
scintillation counter (LS6000IC, Beckman Instruments, Fullerton,
 Calif) at 37°C. Data are reported as counts per minute per 1 mg
protein after background subtraction.

**Microarray Analysis**

Microarrays for 9 weeks of TAC with and without delayed BH4 and
Tempol treatment were performed with the Mouse Genome 430 2.0
array chip (Affymetrix, Santa Clara, Calif). Details are provided in
Methods section of the online Data Supplement.

**Polymerase Chain Reaction Analysis**

Quantitative polymerase chain reaction was performed with an
Applied Biosystems Prism 7900HT Sequence Detection System with
the TaqMan universal polymerase chain reaction master mix accord-
ing to the manufacturer’s specifications (Applied Biosystems Inc,
Foster City, Calif). The Mann-Whitney U test was used to compare
the different groups (SigmaStat, Systat Software, Inc, San Jose,
 Calif). Details are provided in the supplemental Methods.

**Myocardial BH4/BH2 Analysis**

Myocardial BH4 and BH2 levels were determined by direct high-
performance liquid chromatography analysis of frozen tissue homog-
enates. Details are provided in the supplemental Methods.
Statistical Analysis
All data are expressed as mean±SEM. Group data were compared by use of 1- and 2-way ANOVA. Nonparametric data were analyzed with the Kruskal-Wallis test and the Mann-Whitney U test. Reported probability values were Bonferroni or Tukey test adjusted for multiple comparisons (3 to 5 comparisons, depending on the data analyzed). The minimum sample size was 4 for any group; other specific details are provided in the text.

The authors had full access to and take full responsibility for the integrity of the data. All authors have read and agree to the manuscript as written.

Results
BH4 Reverses Chronic Hypertrophic Remodeling and Fibrosis
Four weeks of TAC induced substantial left ventricular remodeling, increasing cardiac mass by 190% and chamber end-diastolic dimension by 140% and lowering fractional shortening by 44% (Figure 1A and 1B). EF declined from 87.4±0.5% to 45.7±1.6% (P<0.001). Hypertrophy reversed and heart function improved in mice that subsequently received BH4 for 5 weeks of continued TAC (Figure 1A and 1B). Chamber dilation was arrested at levels present at the onset of treatment. In contrast, all these features worsened in vehicle-treated mice. Myocyte enlargement and interstitial fibrosis were present at 4 weeks of TAC and were reversed by BH4 treatment (Figure 1C), whereas both remained elevated or worsened in untreated 9-week-TAC mice.

BH4 Prevents Progressive Deterioration of Myocardial Function
Pressure-volume relations were obtained to better assess LV function (Figure 2A and the Table). Rest conditions are reflected by the most rightward pressure-volume loop of each set. At 4 weeks of TAC, hearts were dilated and had increased end-systolic elastance (arrow) typical of hypertrophy. After 9 weeks of TAC, they became markedly dilated and had depressed function (reduced slope [Ees] and right shift of end-systolic pressure-volume relation; the Table). These changes were prevented by BH4, with end-systolic pressure-volume relations maintaining their position at 4 weeks of TAC (ie, onset of treatment; summary data on the right and the Table). Importantly, BH4 did not alter ventricular afterload assessed by peak systolic pressure (Figure 2A, top left) or total resistive load (P=0.3; data not shown).

To further assess the effect of BH4 on myocardial function, myocytes were isolated from treated and untreated 9-week-TAC hearts (Figure 2B). The rate of sarcomere shortening and relengthening improved with BH4 treatment and was associated with higher peak calcium transients and a faster transient decay, consistent with improved calcium cycling.

BH4 Recouples eNOS
As previously reported, 3 to 4 weeks of TAC results in NOS uncoupling indexed by eNOS homodimer instability, reduced Ca²⁺-dependent NOS activity, and increased NOS-derived ROS. Here, we show data for homodimer instability (higher ratio of monomers to dimers in cold SDS nonreducing gels; Figure 3A). Untreated 9-week-TAC mice had persistent instability, with a marked decline in NOS activity and increased NOS-dependent ROS generation (Figure 3B). These behaviors were restored to normal with BH4 treatment. Total eNOS (monomer plus dimer) was unchanged.

In 6 additional animals, BH4 treatment was initiated at the onset of TAC and continued for 9 weeks. After 1 week of TAC, hearts developed nondilated hypertrophy, which was not suppressed by BH4; however, the progressive rise in LV mass and chamber dilation and the decline in EF observed thereafter in controls were prevented by BH4 treatment (Figure 3C; P<0.001 for treatment, time, and treatment-by-time interaction for each parameter based on 2-way ANOVA). This result was consistent with the time course of reduced NOS activity. After 1 week of TAC, in vitro NOS activity remained at control levels, whereas it declined by ≈50% after 3 weeks (Figure 3D), consistent with our earlier report, and even more by 9 weeks (Figure 3B). Thus, BH4 became effective once NOS activity otherwise started to decline.

Effect of BH4 on PKG Activity
Improved eNOS activity could potentially suppress hypertrophy by stimulating downstream PKG. PKG activity rose after 9 weeks of TAC as previously reported with 3 weeks of TAC but was not further enhanced by BH4 treatment (Figure 3E). This was demonstrated by both in vitro activity and phosphorylated vasodilator–stimulated protein immunoblot (Figure 3E, top and bottom, respectively).

Antioxidant Effect of BH4 and Comparison With Tempol
Another potential mechanism of BH4 efficacy is its targeting upstream signaling from NO, the NO-ROS interaction, or ROS itself. Dihydroethidium fluorescent microtopography (Figure 4A) revealed marked ROS generation at 4 and 9 weeks of TAC that fell to nearly control levels with delayed BH4 treatment. This result was confirmed by lucigenin chemiluminescence (Figure 4B).

Given this potent antioxidant effect, we tested whether BH4 therapeutic benefits could be duplicated with a broad antioxidant. With the same delayed-treatment TAC protocol, mice received control diet or food premixed with the nitroxide Tempol (30 to 50 mg/d), a superoxide dismutase mimetic that also suppresses hydroxy, hydrogen peroxide, and other radicals. Both Tempol and BH4 were equally effective in scavenging superoxide in vitro (Figure 4C, left), and Tempol reduced myocardial superoxide potently and similarly to BH4 in TAC hearts (Figure 4C, right; see also Figure 4B). Yet, Tempol did not reverse or prevent progressive hypertrophy (Figure 4D) or affect fibrosis from sustained TAC, and myocyte size declined less than with BH4 (Figure 4E). Tempol increased EF (Figure 4D) by reducing end-systolic dimensions (3.8±0.4 versus 2.8±0.4 mm; P<0.05), so some systolic improvement resulted, although it did not restore eNOS coupling (Figure 4F).

To further probe differences between these therapies, gene-expression microarrays were performed (Table I of the online Data Supplement). Quantitative reverse-transcription polymerase chain reaction was performed on a subset of genes to confirm array results. The 9-week TAC principally
stimulated genes controlling collagen synthesis/degradation and tissue growth factor-β signaling and reduced the expression of genes controlling metabolism. Intriguingly, none of these were significantly offset by BH4 or Tempol. Instead, BH4 increased the expression of genes regulating lipid metabolism (eg, fatty-acid-binding protein 1, apolipoprotein A-1, major urinary protein 1,2) and kallikrein signaling (eg, plasminogen, fibrinogen). Only 8% of these genes were...
similarly affected by BH4 alone (without TAC), and none of these related to lipid metabolism. A more complete list of BH4 modified genes is provided in supplemental Table II. Tempol altered virtually none of the same genes as BH4 but modestly lowered expression of a different set, eg, phospho-
lipase C\textit{\textsubscript{g}}/H9252,1 AMP-kinase\textit{\textsubscript{g}}/H9251, GSK3\textit{\textsubscript{g}}/H9252, mitogen-activated protein-4k3, PKG-1, and flavin-containing monooxygenase 2 (the only gene with similar changes from BH4). Thus, suppressing TAC-induced ROS, more broadly or by a NOS-
targeted strategy, resulted in very different gene profiling and phenotype.

Nonendothelial BH4 Is Central for Its Antihypertrophic Effects

Exogenous BH4 can diffuse into myocytes, fibroblasts, and the vascular endothelium, and because endothelial cells contain 80% of eNOS in the myocardium, this might be the presumed primary target. To test this, we studied mice that overexpressed GCH only in endothelial cells by use of a Tei-2 promoter.\textsuperscript{9} GCH is the rate-limiting enzyme involved in de novo BH4 synthesis, and in this model, isolated myocyte BH4 levels are unaltered,\textsuperscript{9} whereas total myocardial levels rise \textasciitilde4 fold (5.2\pm3.5 to 19.3\pm4.9 pmol/mg protein), similar to the rise achieved by exogenous BH4 (40.5\pm19.1 pmol/mg protein). Intriguingly, chamber hypertrophy, fibrosis, myo-
cyte enlargement, heart function, and dilation changed identically during 12 weeks of TAC in the hearts of GCH-Tg and littermate controls (Figure 5). However, superoxide declined in GCH-Tg myocardium (\textit{P}<0.05), suggesting a role of endothelial NOS uncoupling to myocardial ROS that is less associated with cardiac hypertrophic remodeling. These data indicate that the effectiveness of BH4 to ameliorate pressure-overload cardiac dysfunction and remodeling lies in its targeting of NOS uncoupling in myocytes (and perhaps fibroblasts) rather than in the endothelium.

**Discussion**

The ability of exogenous BH4 to reverse advanced hypertrophic remodeling and to ameliorate heart and myocyte function despite ongoing pressure overload is unusual among existing therapies and suggests that targeting uncoupled eNOS may be a potent and useful strategy for treating hypertrophic heart disease. Few experimental studies involving established advanced disease models have shown the capacity of an intervention to reverse the process. Much of the recent work has relied on genetically engineered models in which the manipulation is generated at or before birth and interventions are initiated at or shortly after the induction of myocardial stress. In clinical trials, however, advanced disease often is required, making the present results notable from
a translational perspective. We specifically targeted pathological hypertension coupled to cardiac decompensation, a period when ROS generation may be particularly important. Drugs such as angiotensin-converting enzyme and receptor blockers blunt disease progression, yet the capacity of BH4 to reverse this pathobiology is striking and supports a detrimental role of NOS uncoupling and the nitroso-redox imbalance.

NOS uncoupling impairs NO synthesis and its downstream effector signaling (ie, cGMP and PKG) while concomitantly increasing ROS generation. Both aspects can trigger myocardial hypertrophy and remodeling. Myocardial PKG signaling coupled to natriuretic peptides or modulation of cGMP catabolism blunts cardiac hypertrophy and can improve heart function. This is thought to be due in part to suppression of calcineurin and nuclear factor of activated T-cell activation; other pathways are likely important also. Because NO stimulates soluble guanylate cyclase to generate cGMP and thus activate PKG, improved NOS function by BH4 could potentially involve this antihypertrophic mechanism. Yet, enhanced PKG activity was not observed, and there are several potential reasons for this. BH4 did not hyperstimulate NOS but returned its activity to normal control levels for which corresponding PKG activation is typically low. PKG activity could have already been maximal, although this is unlikely because enhancing cGMP via PDE5α inhibition (eg, sildenafil) during TAC can potently activate PKG further.

PKG also was activated more with 9 weeks of TAC alone over control (similar to results after 3 weeks of TAC) despite reduced NOS activity, indicating that alternative mechanisms such as cGMP generated by natriuretic peptides (both ANP and BNP expression rose with TAC; see supplemental Table 1) or oxidant stress because this is not observed in normal hearts, itself be expected to stimulate peroxynitrite in the absence of oxidant stress disorders.

An alternative to cGMP/PKG mechanisms is the modulation of NO and NO-ROS interactions by BH4. This would include S-nitrosylation, which can alter cardiac contractile regulation, or local interaction of NOS-derived ROS with NO (forming peroxynitrite) perhaps in a particularly vulnerable subcellular compartment. Recoupling NOS would steer superoxide-derived ROS formation away from peroxide, which may be important. Restored NOS activity would not itself be expected to stimulate peroxynitrite in the absence of oxidant stress because this is not observed in normal hearts, and if anything, BH4 appears to lower peroxynitrite in oxidant stress disorders.

The present data support a growing notion that ROS signaling is compartmentalized and that targeting specific oxidant generators may be more efficacious than broader antioxidant scavengers. Although both Tempol and BH4 provided similar in vitro and tissue (lucigenin) antioxidant effects, their effects on hypertrophy, fibrosis, and NOS...
Figure 3. A, Left, eNOS dimer/monomer gel electrophoresis. Control (Con) tissue has principally dimers in the gel, whereas monomers are more apparent at 4 and 9 weeks of TAC. BH4 restored the control appearance. Relative dimer/monomer density normalized to control is shown in the summary. B, Left, NOS Ca2+/H11001-dependent arginine-citrulline conversion (NOS activity) is reduced after 9 weeks of TAC and restored to normal by BH4. Right, NOS-dependent superoxide determined as the relative lucigenin chemiluminescent signal reduced after blocking NOS (N^G-nitro-L-arginine methyl ester 100 μmol/L). *P<0.01 vs control and 9 weeks treated. C, Effect of BH4 treatment from the onset of TAC over a 9-week period. Hypertrophy generated after 1 week is unaltered, but thereafter, chamber dilation and hypertrophy progression are blocked by BH4 treatment. Statistics from Tukey test based on 2-way ANOVA: *P<0.001 vs control, 1 week, and 9 weeks of TAC, P=0.021 vs untreated and 3 weeks of TAC; **P<0.001 vs other groups and 9 weeks untreated; †P<0.05 vs control, P<0.005 vs 3 and 9 weeks of TAC; ‡P<0.005 vs all other groups, P<0.001 vs untreated; §P<0.02 vs control; §P<0.001 vs control and 9 weeks of TAC; ¶P<0.001 vs untreated. D, NOS activity measured in untreated TAC hearts at 1 and 3 weeks; data shown are normalized to normal control. E, PKG activity increases with 9 weeks of TAC similarly with or without BH4 treatment. Results for in vitro assay (top) and phosphorylated vasodilator-stimulated protein (P-VASP) immunoblot (bottom) are shown.
recoupling were quite different. This is not likely due to an insufficient Tempol dose because the dose used was fairly high (equivalent to 58 mmol/L). It also is the highest dose that mice will tolerate in their food because of the taste. Although clinical trials testing broad antioxidant strategies have been fairly unimpressive to date, this may be analogous to continuously applying sponges to blot up water from an open faucet versus turning the faucet off. The latter, ie, suppressing a strategic ROS source, might well provide more effective results.

There are other oxidant sources in the heart besides uncoupled NOS, although the impact of their inhibition on hypertrophic remodeling remains unclear. Xanthine oxidase–derived free radicals have been found to play a role in dilated cardiac failure, and allopurinol and its active metabolite oxypurinol, which block xanthine oxidase, also improve myocardial efficiency, NO-ROS balance, and myofilament calcium sensitization. However, in clinical trials, these drugs did not improve symptoms or exercise capacity. Furthermore, their role in hypertrophic disease has not been established. NADPH oxidases also have been widely studied. Genetic studies in mice lacking NOX2 (gp91phox) found hypertrophic responses resulting from aortic banding similar to those in controls but somewhat less fibrosis. Other NOX oxidases such as NOX4 may be important, although this remains to be confirmed. Importantly, small-molecule inhibitors remain scant, and none are clinically viable or sufficiently selective at present. Finally, ROS leakage linked to mitochondrial electron transport may also contribute to cardiac failure, although the involvement with pressure-overload hypertrophy remains to be established.

This study has several limitations. Although our data demonstrate that BH4 restores NOS coupling even in advanced hypertrophic heart disease, it does not prove that this is the sole or necessarily primary mechanism underlying the decline in ROS stimulation or amelioration of hypertrophic remodeling and cardiac function. However, the finding that BH4 administered from the onset of TAC did not suppress hypertrophy during the first week (when control heart NOS activity was still preserved) yet prevented progression after that (when NOS uncoupling and reduced activity otherwise occurred) further supports such a link. A second limitation regards the comparison between BH4 and Tempol. Because we did not use a full dose-ranging study, the possibility...
remains that different pharmacology for the 2 compounds and/or alternative signaling not revealed by the data obtained could explain some of the disparate effects.

The present findings suggest that NOS-derived ROS plays a particularly important role in decompensated hypertrophic heart disease. The existing clinical viability of BH4 as a drug, albeit for a different disorder at present, should help facilitate clinical translation and testing of the present findings to human heart disease. An intriguing potential patient population is individuals with heart failure and a preserved EF, often called diastolic heart failure. This disorder affects nearly half of all patients with heart failure worldwide, most often elderly women with hypertension and ventricular hypertrophy, and its prevalence is rising. If the present findings can be translated to humans, BH4 might provide a novel and potent therapy to treat this common heart disease.

Figure 5. A, Mice overexpressing GCH in endothelial cells develop progressive hypertrophy with TAC similar to littermate (non-transgenic [NTG]) controls. Right, Summary data for ratio of heart weight to body weight. B, Transgenic animals develop interstitial fibrosis (*P < 0.05 vs no TAC) and myocyte enlargement (*P < 0.001 vs no TAC) similar to controls. C, TAC-induced decline in EF and increases in wall thickness (WT) and left ventricular end-diastolic and end-systolic dimensions (LVEDD, LVESD) were virtually identical in GCH-Tg and littermate controls. D, Superoxide increases significantly more in NTG than in GCH-Tg mice subjected to 12 weeks of TAC.

Sustained pressure overload induces profound ventricular remodeling and is a leading cause of cardiac failure. An important mechanism for this maladaptive response is stimulation of reactive oxygen species, and recent studies indicate that functional uncoupling of nitric oxide synthase (NOS) plays an important role in this pathophysiology. A key determinant of NOS coupling, and thus its generation of NO versus O$_2$–, is the level and redox state of its cofactor tetrahydrobiopterin (BH$_4$), which becomes compromised from pressure-overload stress. Here, we tested whether exogenous administration of BH$_4$ could restore NOS coupling and function, reduce oxidant stress, and block or reverse maladaptive remodeling in hearts with already advanced disease induced by pressure overload. In mice subjected to proximal aortic constriction, BH$_4$ stopped progressive chamber dilation and dysfunction, reversed fibrosis and hypertrophy, and improved myocyte function and calcium handling. NOS became recoupled, and oxidant stress potently declined. The effects of BH$_4$ were linked to NO–reactive oxygen species interactions and became manifest when NOS activity started to decline after induction of pressure overload. Parallel studies performed with a broad antioxidant (Tempol) did not replicate BH$_4$ effects on reverse remodeling even though oxidant stress was reduced. Furthermore, selective enhancement of BH$_4$ in endothelial cells did not mimic the response to exogenous BH$_4$, highlighting the importance of myocyte NOS uncoupling. These findings support the potential therapeutic utility of BH$_4$ as a treatment for advanced hypertrophic heart disease. They also highlight the notion that not all antioxidant strategies are equivalent and that targeting NOS uncoupling could prove to be a particularly potent approach.
Reversal of Cardiac Hypertrophy and Fibrosis From Pressure Overload by Tetrahydrobiopterin: Efficacy of Recoupling Nitric Oxide Synthase as a Therapeutic Strategy
