Calcium-Activated Potassium Channels Contribute to Human Coronary Microvascular Dysfunction After Cardioplegic Arrest

Jun Feng, MD, PhD; Yuhong Liu, MD; Richard T. Clements, PhD; Neel R. Sodha, MD; Kamal R. Khabbaz, MD; Venkatachalam Senthilnathan, MD; Katherine K. Nishimura, BA; Seth L. Alper, MD, PhD; Frank W. Sellke, MD

Background—Cardioplegic arrest (CP) followed by reperfusion after cardiopulmonary bypass induces coronary microvascular dysfunction. We investigated the role of calcium-activated potassium (KCa) channels in this dysfunction in the human coronary microvasculature.

Methods and Results—Human atrial tissue was harvested before CP from a nonischemic segment and after CP from an atrial segment exposed to hyperkalemic cold blood CP (mean CP time, 58 minutes) followed by 10-minute reperfusion. In vitro relaxation responses of precontracted arterioles (80 to 180 μm in diameter) in a pressurized no-flow state were examined in the presence of KCa channel activators/blockers and several other vasodilators. We also examined expression and localization of KCa channel gene products in the coronary microvasculature using reverse transcriptase–polymerase chain reaction, immunoblot, and immunofluorescence photomicroscopy. Post-CP reperfusion relaxation responses to the activator of intermediate and small conductance KCa channels (IKCa/SKCa), NS309 (10−5 M), and to the endothelium-dependent vasodilators, substance P (10−8 M) and adenosine 5′ diphosphate (10−5 M), were significantly reduced compared with pre-CP responses (P<0.05, n=8/group). In contrast, relaxation responses to the activator of large conductance KCa channels (BKCa), NS1619 (10−5 M), and to the endothelium-independent vasodilator, sodium nitroprusside (10−4 M), were unchanged pre- and post-CP reperfusion (n=8/group). Endothelial denudation significantly diminished NS309-induced vasodilatation and abolished substance P- or adenosine 5′ diphosphate-induced relaxation (P<0.05), but had no effect on relaxation induced by either NS1619 or sodium nitroprusside. The total polypeptide levels of BKCa, IKCa, and SKCa and the expression of IKCa mRNA were not altered post-CP reperfusion.

Conclusion—Cardioplegic arrest followed by reperfusion after cardiopulmonary bypass causes microvascular dysfunction associated with and likely in part due to impaired function of SKCa and IKCa channels in the coronary microcirculation. These results suggest novel mechanisms of endothelial and smooth muscle microvascular dysfunction after cardiac surgery. (Circulation. 2008;118[suppl 1]:S46–S51.)

Key Words: calcium-activated potassium channels ■ cardioplegia ■ ischemia and reperfusion ■ microcirculation

Microvascular endothelial dysfunction and altered vascular reactivity often occur after ischemic arrest and cardiopulmonary bypass, although cardioplegia has been routinely used for the protection of the myocardium against ischemic injury during cardiac surgery.1-3 Endothelium has been found to release 3 major endothelium-dependent relaxing factors: nitric oxide, prostacyclin, and endothelium-dependent hyperpolarization factor (EDHF).4 Impaired endothelial synthesis and release of nitric oxide, prostacyclin, and EDHF associated with cardiopulmonary ischemia and reperfusion may contribute to microvascular endothelial dysfunction.1-3 These observations have prompted addition to cardiopulmonary solutions of nitric oxide donors, exogenous prostacyclin, and EDHF agonists in attempts to attenuate ischemia/reperfusion-mediated endothelial dysfunction.5-7 The vasodilatory influence of EDHF is believed predominant in smaller arterioles.

EDHF has been proposed to dilate the coronary arteries through opening of calcium-activated potassium channels (KCa) in endothelial and smooth muscle cells.4 Recently, we found that bradykinin preconditioning of coronary microvasculature in isolated rabbit hearts undergoing cardioplegic arrest was mediated in part by the activation of KCa channels.8 However, the roles of KCa channel activation in cardioplegic arrest (CP) and reperfusion-related microvascular dysfunction in human coronary resistance arterioles and the regula-

S46
tory properties of these KCa channels in this vascular bed have little been investigated.

This study was designed to examine the effect of blood CP and brief reperfusion (Rep) on vascular responses of human atrial microvessels to KCa channel openers and other vasoactive substances and to correlate these responses to possible alterations in expression of KCa channel mRNAs and polypeptides in human atrial tissue.

Materials and Methods

Human Subjects and Tissue Harvesting

Samples of right atrial appendage were harvested from clinically similar patients undergoing coronary artery bypass graft surgery before and after exposure of the heart to blood CP and short-term reperfusion under conditions of cardiopulmonary bypass. Samples were harvested with cold sharp dissection and handled in a nontraumatic fashion. Double 3-0 polypropylene pursestring sutures (Ethicon, Somerville, NJ) were placed in the atrial appendage. During placement of the venous cannula, the first sample of atrial appendage was harvested before cardioplegia and reperfusion (pre-CP Rep). The superior suture was tightened to secure the venous cannula. The inferior suture remained loose to allow this portion of the atrium to be perfused with blood, exposed to blood CP, and reperfused (post-CP Rep) after removal of the aortic crossclamp. An initial 800 to 1000 mL of cold-blood (0°C to 4°C) hyperkalemic (15 mmol/L) K+ cardioplegic solution was delivered antegrade into the atrial root. This was followed at 8- to 15-minute intervals with 250 to 300 mL of cold CP solution (15 mmol/L K+). The CP solutions consisted of a mixture of oxygenated blood with crystalloid solution of the following final composition (in mmol/L): 15 KCl, 3.5 MgSO4, 135NaCl, 1.0 CaCl2, 11 glucose, 11 mannnitol, and 4 tromethamine.

The second sample of atrial appendage was harvested during removal of the venous cannula. Tissue samples for immunoblot analysis assay were immediately frozen in liquid nitrogen. Tissue for immunofluorescent staining was fixed in 10% formalin-buffered phosphate-buffered saline and incubated with the appropriate Alexa fluorophore, and RNA concentration was estimated by absorbance at 260 nm. Reverse transcription was performed with the First Strand cDNA Synthesis Kit (Ambion, Austin, Texas) using equal amounts of total RNA. Five percent of the cDNA mixture was used for polymerase chain reaction with HotStart DNA Polymerase (Qiagen; total reaction volume 20 µL in supplier’s recommended buffer). Two primer pairs tested yielded nearly identical results: forward primer IK1.F6 5’-GGAAAGCTCCGGAGAACAGTG-3’ coupled with reverse primer IKCa.R3 5’-CTACTTGACGTGGCAGTGGTCTC-3’ (209 bp polymerase chain reaction product) or forward primer IK1.F7 5’-GGTGACATCATTCCAAGATGCAC-3’ coupled with the same reverse primer (181 bp polymerase chain reaction product). Complete reaction mixes were incubated 15 minutes at 95°C, then cycled through 45 seconds denaturation at 94°C, 2 minutes annealing at 60°C, and 2 minutes elongation at 72°C. A 7-minute final extension at 72°C was terminated by rapid cooling to room temperature. Polymerase chain reaction products were separated in 1% agarose gels, visualized with ethidium bromide, and imaged (GelDoc; BioRad, Hercules, Calif). Polymerase chain reaction cycle number was adjusted to achieve low abundance transcript detection within the range of log linear amplification. Thirty-six cycles were chosen for amplification of IKCa transcript and 23 cycles for β-actin controls.

Coronary Microvessel Relaxation Studies

Coronary arterioles (80- to 180-µm internal diameters) were dissected from the right atria appendage pre- and post-CP Rep. Microvessel studies were performed by in vitro organ bath videomicroscopy as described previously.3,6 After a 60-minute stabilization period in the organ chamber, the microvessels were reconstituted with thromboxane A2 analog U46619×30% to 40% of the baseline diameter. After achievement of this constricted steady state, dose-dependent relaxation was measured in response to (extraluminal) perfusion of the following vasodilators: the activator of intermediate and small conductance KCa channels ( IKCa/SKCa), NS309, the activator of large conductance KCa channels (BKCa), NS1619 (both from 10-9 to 10-3 M), nitrogen nitroprusside (SNP), adenosine 5’-diphosphate (both from 10-9 to 10-4 M), and substance P (10-12 to 10-7 M). After exposure to substance P, the vessel was discarded to avoid tachyphylaxis. One or 3 interventions were performed on each vessel. The order of drug administration was random. Six vessels harvested before CP Rep were pretreated with a mixture of the IKCa blocker, TRAM34 (10-7 M), and the SKCa blocker, apamin (10-8 M), before perfusion with NS309. Six additional vessels were pretreated with the BKCa blocker, iberiotoxin (10-7 M) before perfusion with NS1619. In some cases, endothelial denudation was carried out by advancing a human hair into the lumen and gently abrading the luminal surface.

Immunoblot

Small coronary arteries were dissected and cleaned of connective tissues and solubilized in SDS-PAGE buffer. Total protein (40 µg) was fractionated on an 8% to 16% SDS-PAGE and then transferred to a polyvinylidene difluoride membrane (Immobilon-P; Millipore Corporation, Bedford, Mass) as previously described.3 Membranes were incubated for 1 hour at room temperature with 1:200 dilutions of individual rabbit polyclonal primary antibodies to BKCa-α, BKCa-β1 (Santa Cruz Biotechnology, Santa Cruz, Calif), IKCa, or SKCa-α (Alomone Labs Ltd, Jerusalem, Israel). The membranes were then incubated for 1 hour with horseradish peroxidase-conjugated secondary anti-Ig, washed 3× in Tris saline buffer, and processed for chemiluminescent detection (Pierce, Rockford, III) on x-ray film (Kodak, Rochester, NY). Band intensity was measured by densitometric analysis of autoradiograph films using NIH Image J.33. Specificities of the anti-BKCa-α, anti-BKCa-β1, anti-IKCa, and anti-SKCa-α antibodies were demonstrated in the previous studies, respectively.8–10

Reverse Transcriptase–Polymerase Chain Reaction of IKCa mRNA

Total RNA was prepared with the RNeasy kit (Qiagen, Valencia, Calif) from flash-frozen pre- and post-CP Rep atrial tissue samples. RNA integrity was verified by formaldehyde-agarose gel electrophoresis, and RNA concentration was estimated by absorbance at 260 nm. Reverse transcription was performed with the First Strand cDNA Synthesis Kit (Ambion, Austin, Texas) using equal amounts of total RNA. Five percent of the cDNA mixture was used for polymerase chain reaction with HotStart DNA Polymerase (Qiagen; total reaction volume 20 µL in supplier’s recommended buffer). Two primer pairs tested yielded nearly identical results: forward primer IK1.F6 5’-GGAAAGCTCCGGAGAACAGTG-3’ coupled with reverse primer IKCa.R3 5’-CTACTTGACGTGGCAGTGGTCTC-3’ (209 bp polymerase chain reaction product) or forward primer IK1.F7 5’-GGTGACATCATTCCAAGATGCAC-3’ coupled with the same reverse primer (181 bp polymerase chain reaction product). Complete reaction mixes were incubated 15 minutes at 95°C, then cycled through 45 seconds denaturation at 94°C, 2 minutes annealing at 60°C, and 2 minutes elongation at 72°C. A 7-minute final extension at 72°C was terminated by rapid cooling to room temperature. Polymerase chain reaction products were separated in 1% agarose gels, visualized with ethidium bromide, and imaged (GelDoc; BioRad, Hercules, Calif). Polymerase chain reaction cycle number was adjusted to achieve low abundance transcript detection within the range of log linear amplification. Thirty-six cycles were chosen for amplification of IKCa transcript and 23 cycles for β-actin controls.

Immunofluorescence Photomicroscopy

Atrial tissue sections from 5 patients were deparaffinized in xylene, rehydrated in graded ethanol and phosphate-buffered saline solution, and antigen-unmasked with sodium citrate (10 mmol/L, pH=6.0) followed by phosphate-buffered saline wash and blocking with 2% bovine serum albumin in phosphate-buffered saline at room temperature for 2 hours. After phosphate-buffered saline wash, overnight incubation with anti-BKCa-α and BKCa-β1 (each used 1:200; Santa Cruz Biotechnology) was performed at 4°C. A mouse, α-smooth muscle actin (1:1000; Sigma, St Louis, Mo) was used to detect microvascular smooth muscle. Sections were then washed in phosphate-buffered saline and incubated with the appropriate Alexa fluor secondary antibody and mounted using fluorescent mounting medium (Vector Labs, Burlingame, Calif). Tissue was visualized using a Zeiss LSM510 confocal microscope system (Carl Zeiss Microimaging, Inc, Thornwood, NY). Tissue labeling with secondary antibody alone or with normal rabbit IgG or serum in place of primary antibody served as a negative control.

Chemicals

NS309, NS1619, U46619, SNP, adenosine 5’-diphosphate (ADP), and substance P were obtained from Sigma. SNP, ADP, and substance P were dissolved in ultrapure distilled water and prepared.
on the day of the study. U46619 was dissolved in ethanol to make a stock solution. NS309 and NS1619 were dissolved in dimethylsulfox- oxidize to make a stock solution. All stock solutions were stored at
−20°C. All dilutions were prepared daily.

Data Analysis
Data are presented as the mean and SEM. The relaxation responses
were expressed as the percentage of relaxation of the U46619-
preconstricted diameter of the microvessels. Repeated-measures
analysis of variance and Student t test were used to compare
variables between or among vessels. The treatment effects were
statistically examined by paired or independent 2-tailed Student t
test. Statistical significance was taken at a probability value of
<0.05.

Statement of Responsibility
The authors had full access to the data and take full responsibility for
its integrity. All authors have read and agree to the manuscript as
written.

Results

Patient Characteristics
Tissue samples from 27 patients were studied. Twenty-seven
patients (mean age 67±6 years) underwent coronary artery
bypass graft with duration of cardiopulmonary arrest of 58±4
minutes and cardiopulmonary bypass time of 71.0±18 min-
utes. Twenty-one patients were male and 6 were female.
Twenty-two of the 27 patients carried a preoperative diagno-
sis of hypertension. All patients with preoperative hyperten-
sion (type I or type II) was present in 5 of 27 patients.

Vessel Characteristics
Coronary microvessels ranged from 80 to 180 μm in internal
diameter. Diameters in the NS309 groups were 107±4 μm in the
pre-CP Rep group, 110±8 μm in the post-CP Rep group,
103±7 μm in the endothelium denudation group, and
137±9 μm in the TRAM34/apamin+NS309 group. Diam-
eters in the NS1619 groups were 125±10 μm in the pre-CP
Rep group, 114±9 μm in the post-CP Rep group,
146±11 μm in the endothelium denudation group, and
126±8 μm in the iberiotoxin+NS1619 group. In the sub-
stance P groups, diameters were 134±6 μm in the pre-CP
Rep group, 112±7 μm in the post-CP Rep group, and
119±7 μm in the endothelium denudation group. In the ADP
groups, diameters were 118±10 μm in the pre-CP Rep group,
130±12 μm in the post-CP Rep group, and 135±7 μm in the
endothelium denudation group. In the SNP groups, diameters
were 116±6 μm in the pre-CP Rep group, 108±7 μm in the
pre-CP Rep group, and 122±11 μm in the endothelium
denudation group. Most intergroup differences of the vessel
diameters were statistically insignificant. The degree of
precontraction by the thromboxane A2 analog U46619 was
29±2% in the pre-CP Rep group and 31±2% in the post-CP
Rep group. Similar U46619 concentrations were required to
produce adequate precontraction in both groups.

Responses to NS309 and NS1619
Both NS309 (Figure 1A) and NS1619 (Figure 2A) induced
dose-dependent relaxation of human coronary arterioles.
Cardioplegic arrest and reperfusion significantly impaired the
relaxation response to NS 309 compared with pre-CP Rep
responses (P<0.05; Figure 1A). In contrast, the pre-CP Rep
responses to NS1619 were unchanged post-CP Rep (Figure
2A). Pretreatment with TRAM34/apamin abolished vessel
relaxation induced by NS309 (P<0.001; Figure 1B), and
NS1619-induced relaxation was inhibited by pretreatment
with iberiotoxin (P<0.001; Figure 2B). Furthermore, NS309-
m ediated vasorelaxation of the coronary arterioles was sig-
nificantly diminished by removal of the endothelium
(P<0.001; Figure 1C), whereas responses to NS1619 were
unaffected (Figure 2C).

Responses to Adenosine 5’ Diphosphate, Substance
P, and Sodium Nitroprusside
ADP, substance P, and SNP induced dose-dependent relaxa-
tion of coronary arterioles (Figure 3A–C). Cardioplegic
arrest and reperfusion remarkably reduced the relaxation
responses both to ADP and to substance P compared with
pre-CP Rep responses (P<0.05; Figure 3A–B). In contrast,
pre-CP Rep responses to SNP were unchanged post-CP Rep
(Figure 3C). Endothelium denudation abolished responses to
both ADP and substance P (P<0.001; Figure 3A–B), but left
intact SNP-induced relaxation.
Effect of Cardioplegic Arrest Reperfusion on levels of KCa Polypeptides and IKCa mRNA

Pre-CP Rep coronary artery levels of the KCa channel polypeptides BKCa-α and BKCa, BKCa-β1, IKCa-α, and SK3Ca-α were unchanged in the post-CP Rep period as detected by immunoblot (Figure 4A–B). Levels of IKCa mRNA were similarly unaltered after cardioplegic ischemia and reperfusion (Figure 4C).

Immunolocalization of Microvessel KCa Polypeptides Pre- and Postcardioplegic Arrest Reperfusion

Immunofluorescent staining of coronary microvessels displayed a strong signal for BKCa-α (Figure 5A) and BKCa-β1 (Figure 5B) subunits localized to the microvascular smooth muscle and less abundantly to endothelium. Negative controls documented low-level background fluorescence.

Discussion

This study presents several novel findings. First, both the IKCa/SKCa activator NS309 and the BK Ca-specific opener NS1619 induced dose-dependent vasodilatation of human coronary arterioles. Second, the relaxation response to NS309 was significantly impaired after CP and Rep, whereas the response to NS1619 was unaltered. Third, the response to NS309 was significantly diminished after endothelium denudation, whereas the response to NS1619 was unaffected. Fourth, the presence of BKCa, IKCa, and SKCa polypeptides in human coronary microvasculature was documented by immunoblot and by immunofluorescence microscopy. BKCa immunostaining was present predominantly in smooth muscle cells and less apparent in endothelium. However, SKCa immunostaining was detected predominantly in endothelium and less in smooth muscle cells. IKCa mRNA was also present in human atrial tissue. Finally, cardioplegic ischemia and Rep change neither total polypeptide levels of BKCa, IKCa, or SKCa polypeptides nor the level of IKCa mRNA.

We and several others have previously shown that cardioplegic ischemia and Rep resulted in microvascular endothelial dysfunction and decreased hyperpolarization in animals and humans. The present study confirmed previous findings indicating that responses to several endothelium-dependent vasodilators such as ADP and substance P were significantly reduced after cardioplegic ischemia and Rep. Recent studies have demonstrated that KCa channels contribute to the vasodilatation and hyperpolarization induced by the EDHF stimulators, substance P and bradykinin. Three types of KCa channels, BKCa, IKCa, and SKCa, are present in the vasculature. In the present study, relaxation responses to NS309 were completely blocked in the combined presence of the IKCa blocker TRAM 34 and the SKCa inhibitor apamin, supporting specificity of NS309 as an activator of both IKCa.
and SK_{\text{Ca}} channels. Relaxation responses to NS1619 were abolished in the presence of the BK_{\text{Ca}} blocker iberiotoxin, consistent with the specificity of NS1619 as a BK_{\text{Ca}} activator. Endothelium denudation significantly diminished NS309-induced relaxation but failed to affect the response to NS1619. These results show that whereas NS309-induced relaxation is endothelium-dependent, relaxation induced by NS1619 is endothelium-independent. Another important finding of the present study is that cardioplegic ischemia and Rep remarkably impaired IK_{\text{Ca}}/SK_{\text{Ca}} channel activator NS309-induced dose-dependent vasodilatation, but not the BK_{\text{Ca}} opener NS1619-induced relaxation, suggesting that the inactivation of IK_{\text{Ca}}/SK_{\text{Ca}} may be involved in endothelial dysfunction of human coronary microvasculature. All the results presented were obtained in vessels precontracted with a thromboxane agonist. It is thus possible that the proportional vasodilatory contributions of IK_{\text{Ca}}/SK_{\text{Ca}} and BK_{\text{Ca}} channels may vary in coronary microvessels precontracted by other agonists such as endothelin, norepinephrine, or elevated extracellular calcium.

To detect IK_{\text{Ca}}/SK_{\text{Ca}} and BK_{\text{Ca}} gene products in the human coronary microvasculature, we performed immunoblot and immunohistochemistry to localize channel polypeptides. We found that BK_{\text{Ca}} was predominantly present in smooth muscle cells. This finding is consistent with the microvessel relaxation data, indicating that BK_{\text{Ca}} activator-mediated relaxation is endothelium-independent. BK_{\text{Ca}}, IK_{\text{Ca}}, and SK_{\text{Ca}} polypeptides were detected by immunoblot of extracts from human coronary microvessels. IK_{\text{Ca}} mRNA was detected in human atrial appendage. However, cardioplegic ischemia and Rep did not alter expression of BK_{\text{Ca}}, IK_{\text{Ca}}, and SK_{\text{Ca}} polypeptides or IK_{\text{Ca}} mRNA levels, suggesting that short periods of intraoperative hypothermic ischemia and reperfusion may modify the functional state of channel protein activation or intracellular distribution rather than the steady-state levels of protein and (in the case of IK_{\text{Ca}}) mRNA.

The molecular mechanisms responsible for the CP Rep-related IK_{\text{Ca}}/SK_{\text{Ca}} channel dysfunction remain unclear. Ischemia and Rep may induce activation and phosphorylation of several protein and tyrosine kinases, which in turn may phosphorylate IK_{\text{Ca}}/SK_{\text{Ca}} channels or their regulatory proteins, resulting in channel inactivation\textsuperscript{13} either by decreasing open probability or by reduction of channel number at the cell surface. Generation of free radicals and cytokine release during ischemia and Rep may also inhibit K_{\text{Ca}} channel activity.\textsuperscript{14}

In conclusion, CP followed by Rep after cardiopulmonary bypass causes microvascular dysfunction, likely due in part to impaired function of IK_{\text{Ca}}/SK_{\text{Ca}} channels in human coronary microcirculation. These results may provide novel mechanisms by which to explain the presently unavoidable endothelial and smooth muscle microvascular dysfunction after cardiac surgery. Pharmacological administration of K_{\text{Ca}} openers may represent a novel strategy to improve microvascular protection during cardiac surgery and minimally invasive revascularization.
