A 35-year-old woman with a history of disseminated thoracic echinococcosis treated by resection of an intra-ventricular septal cyst 11 years earlier in her country of origin presented for the first time to our cardiology outpatient clinic with atypical chest pain and shortness of breath. Transthoracic echocardiography revealed multiple masses in the pericardium (Figure 1); chest x-ray showed widening of the right middle mediastinum (Figure 2). Computed tomography imaging and T2-weighted turbo spin echo were performed and confirmed the infiltration of the pericardium by multiple cysts (Figure 3). In addition, a saccular aortic pseudoaneurysm of the ascending aorta (Figures 4 and 5) was revealed and confirmed by aortography (Figure 6 and Movie I in the online-only Data Supplement). We hypothesized that the pseudoaneurysm developed subsequently to fistulization and rupture of a hydatid cyst into the aorta. Indeed, the patient reported having presented an anaphylactic shock several months earlier while living abroad. Given the potential risk of rupture of the aortic pseudoaneurysm, we referred the patient to redo surgery.

At surgery, hypertonic serum (20% saline) was injected into the cysts before their removal, and minimal cardiac manipulation was performed to avoid cestode dissemination. Repair of the aortic aneurysm was performed with a Dacron prosthesis. Histopathology confirmed that the pseudoaneurysm of the aorta resulted from a hydatid cyst. The patient’s subsequent recovery was uneventful under anthelmintics comprising albendazole and biltricide.

Cardiac involvement in patients diagnosed with hydatidosis is uncommon. Thus, evidence-based therapy is lacking even if surgical management seems to be associated with a better outcome of patients. In our case, surgery was mandated by the fistulization of a cyst into the aorta, resulting in a pseudoaneurysm threatening to rupture. To the best of our knowledge, such fistulization of a hydatid cyst into the aorta has not yet been described.

Disclosures

None.
