PREAMBLE

Since 1980, the American College of Cardiology (ACC) and American Heart Association (AHA) have translated scientific evidence into clinical practice guidelines with recommendations to improve cardiovascular health. These guidelines, based on systematic methods to evaluate and classify evidence, provide a cornerstone of quality cardiovascular care.

In response to reports from the Institute of Medicine1,2 and a mandate to evaluate new knowledge and maintain relevance at the point of care, the ACC/AHA Task Force on Clinical Practice Guidelines (Task Force) modified its methodology.3-5 The relationships among guidelines, data standards, appropriate use criteria, and performance measures are addressed elsewhere.3

Intended Use

Practice guidelines provide recommendations applicable to patients with or at risk of developing cardiovascular disease. The focus is on medical practice in the United States, but guidelines developed in collaboration with other organizations may have a broader target. Although guidelines may be used to inform regulatory or payer decisions, the intent is to improve quality of care and align with patients’ interests. Guidelines are intended to define practices meeting the needs of patients in most, but not all, circumstances, and should not replace clinical judgment. Guidelines are reviewed annually by the Task Force and are official policy of the ACC and AHA. Each guideline is considered current until it is updated, revised, or superseded by published addenda, statements of clarification, focused updates, or revised full-text guidelines. To ensure that guidelines remain current, new data are reviewed biannually to determine whether recommendations should be modified. In general, full revisions are posted in 5-year cycles.3-6

Modernization

Processes have evolved to support the evolution of guidelines as “living documents” that can be dynamically updated. This process delineates a recommendation to address a specific clinical question, followed by concise text (ideally <250 words) and hyperlinked to support-
ive evidence. This approach accommodates time constraints on busy clinicians and facilitates easier access to recommendations via electronic search engines and other evolving technology.

Evidence Review

Writing committee members review the literature; weigh the quality of evidence for or against particular tests, treatments, or procedures; and estimate expected health outcomes. In developing recommendations, the writing committee uses evidence-based methodologies that are based on all available data. Literature searches focus on randomized controlled trials (RCTs) but also include registries, nonrandomized comparative and descriptive studies, case series, cohort studies, systematic reviews, and expert opinion. Only selected references are cited.

The Task Force recognizes the need for objective, independent Evidence Review Committees (ERCs) that include methodologists, epidemiologists, clinicians, and biostatisticians who systematically survey, abstract, and assess the evidence to address systematic review questions posed in the PICOTS format (P=population, I=intervention, C=comparator, O=outcome, T=timing, S=setting). Practical considerations, including time and resource constraints, limit the ERCs to evidence that is relevant to key clinical questions and lends itself to systematic review and analysis that could affect the strength of corresponding recommendations.

Guideline-Directed Management and Treatment

The term “guideline-directed management and therapy” (GDMT) refers to care defined mainly by ACC/AHA Class I recommendations. For these and all recommended drug treatment regimens, the reader should confirm dosage with product insert material and carefully evaluate for contraindications and interactions. Recommendations are limited to treatments, drugs, and devices approved for clinical use in the United States.

Class of Recommendation and Level of Evidence

The Class of Recommendation (COR; ie, the strength of the recommendation) encompasses the anticipated magnitude and certainty of benefit in proportion to risk. The Level of Evidence (LOE) rates evidence supporting the effect of the intervention on the basis of the type, quality, quantity, and consistency of data from clinical trials and other reports (Table 1). Unless otherwise stated, recommendations are sequenced by COR and then by LOE. Where comparative data exist, preferred strategies take precedence. When >1 drug, strategy, or therapy exists within the same COR and LOE and no comparative data are available, options are listed alphabetically.

Relationships With Industry and Other Entities

The ACC and AHA sponsor the guidelines without commercial support, and members volunteer their time. The Task Force zealously avoids actual, potential, or perceived conflicts of interest that might arise through relationships with industry or other entities (RWI). All writing committee members and reviewers are required to disclose current industry relationships or personal interests, from 12 months before initiation of the writing effort. Management of RWI involves selecting a balanced writing committee and assuring that the chair and a majority of committee members have no relevant RWI (Appendix 1). Members are restricted with regard to writing or voting on sections to which their RWI apply. For transparency, members’ comprehensive disclosure information is available online. Comprehensive disclosure information for the Task Force is also available online.

The Task Force strives to avoid bias by selecting experts from a broad array of backgrounds representing different geographic regions, sexes, ethnicities, intellectual perspectives/biases, and scopes of clinical practice, and by inviting organizations and professional societies with related interests and expertise to participate as partners or collaborators.

Individualizing Care in Patients With Associated Conditions and Comorbidities

Managing patients with multiple conditions can be complex, especially when recommendations applicable to coexisting illnesses are discordant or interacting. The guidelines are intended to define practices meeting the needs of patients in most, but not all, circumstances. The recommendations should not replace clinical judgment.

Clinical Implementation

Management in accordance with guideline recommendations is effective only when followed. Adherence to recommendations can be enhanced by shared decision making between clinicians and patients, with patient engagement in selecting interventions on the basis of individual values, preferences, and associated conditions and comorbidities. Consequently, circumstances may arise in which deviations from these guidelines are appropriate.

Jonathan L. Halperin, MD, FACC, FAHA
Chair, ACC/AHA Task Force on Clinical Practice Guidelines

1. INTRODUCTION

1.1. Methodology and Evidence Review

The recommendations listed in this guideline are, whenever possible, evidence based. An initial extensive evidence review, which included literature derived from
research involving human subjects, published in English, and indexed in MEDLINE (through PubMed), EMBASE, the Cochrane Library, the Agency for Healthcare Research and Quality, and other selected databases relevant to this guideline, was conducted from January through September 2015. Key search words included but were not limited to the following: acute limb ischemia, angioplasty, ankle-brachial index, anticoagulation, antiplatelet therapy, atypical leg symptoms, blood pressure lowering/hypertension, bypass graft/bypass grafting/surgical bypass, cilostazol, claudication/intermittent claudication, critical limb ischemia/severe limb ischemia, diabetes, diagnostic testing, endovascular therapy, exercise rehabilitation/exercise therapy/exercise training/supervised exercise, lower extremity/foot wound/ulcer, peripheral artery disease/peripheral arterial disease/
peripheral vascular disease/lower extremity arterial disease, smoking/smoking cessation, statin, stenting, and vascular surgery. Additional relevant studies published through September 2016, during the guideline writing process, were also considered by the writing committee, and added to the evidence tables when appropriate. The final evidence tables included in the Online Data Supplement summarize the evidence utilized by the writing committee to formulate recommendations. Additionally, the writing committee reviewed documents related to lower extremity peripheral artery disease (PAD) previously published by the ACC and AHA. References selected and published in this document are representative and not all-inclusive.

As stated in the Preamble, the ACC/AHA guideline methodology provides for commissioning an independent ERC to address systematic review questions (PI-COTS format) to inform recommendations developed by the writing committee. All other guideline recommendations (not based on the systematic review questions) were also subjected to an extensive evidence review process. For this guideline, the writing committee in conjunction with the Task Force and ERC Chair identified the following systematic review questions: 1) Is antiplatelet therapy beneficial for prevention of cardiovascular events in the patient with symptomatic or asymptomatic lower extremity PAD? 2) What is the effect of revascularization, compared with optimal medical therapy and exercise training, on functional outcome and quality of life (QoL) among patients with claudication? Each question has been the subject of recently published, systematic evidence reviews. The quality of these evidence reviews was appraised by the ACC/AHA methodologist and a vendor contracted to support this process (Doctor Evidence [Santa Monica, CA]). Few substantive randomized or nonrandomized studies had been published after the end date of the literature searches used for the existing evidence reviews, so the ERC concluded that no additional systematic review was necessary to address either of these critical questions.

A third systematic review question was then identified: 3) Is one revascularization strategy (endovascular or surgical) associated with improved cardiovascular and limb-related outcomes in patients with critical limb ischemia (CLI)? This question had also been the subject of a high-quality systematic review that synthesized evidence from observational data and an RCT: additional RCTs addressing this question are ongoing. The writing committee and the Task Force decided to expand the survey to include more relevant randomized and observational studies. Based on evaluation of this additional evidence the ERC decided that further systematic review was not needed to inform the writing committee on this question. Hence, the ERC and writing committee concluded that available systematic reviews could be used to inform the development of recommendations addressing each of the 3 systematic review questions specified above. The members of the Task Force and writing committee thank the members of the ERC that began this process and their willingness to participate in this volunteer effort. They include Aruna Pradhan, MD, MPH (ERC Chair); Natalie Evans, MD; Peter Henke, MD; Dharam J. Kumbhani, MD, SM, FACC; and Tamar Polonsky, MD.

1.2. Organization of the Writing Committee

The writing committee consisted of clinicians, including noninvasive and interventional cardiologists, exercise physiologists, internists, interventional radiologists, vascular nurses, vascular medicine specialists, and vascular surgeons, as well as clinical researchers in the field of vascular disease, a nurse (in the role of patient representative), and members with experience in epidemiology and/or health services research. The writing committee included representatives from the ACC and AHA, American Association of Cardiovascular and Pulmonary Rehabilitation, Inter-Society Consensus for the Management of Peripheral Arterial Disease, Society for Cardiovascular Angiography and Interventions, Society for Clinical Vascular Surgery, Society of Interventional Radiology, Society for Vascular Medicine, Society for Vascular Nursing, Society for Vascular Surgery, and Vascular and Endovascular Surgery Society.

1.3. Document Review and Approval

This document was reviewed by 2 official reviewers nominated by the ACC and AHA; 1 to 2 reviewers each from the American Association of Cardiovascular and Pulmonary Rehabilitation, Inter-Society Consensus for the Management of Peripheral Arterial Disease, Society for Cardiovascular Angiography and Interventions, Society for Clinical Vascular Surgery, Society of Interventional Radiology, Society for Vascular Medicine, Society for Vascular Nursing, Society for Vascular Surgery, and Vascular and Endovascular Surgery Society; and 16 additional individual content reviewers. Reviewers’ RWI information was distributed to the writing committee and is published in this document (Appendix 2).

This document was approved for publication by the governing bodies of the ACC and the AHA and endorsed by the American Association of Cardiovascular and Pulmonary Rehabilitation, Inter-Society Consensus for the Management of Peripheral Arterial Disease, Society for Cardiovascular Angiography and Interventions, Society for Clinical Vascular Surgery, Society of Interventional Radiology, Society for Vascular Medicine, Society for Vascular Nursing, Society for Vascular Surgery, and Vascular and Endovascular Surgery Society.
1.4. Scope of Guideline

Lower extremity PAD is a common cardiovascular disease that is estimated to affect approximately 8.5 million Americans above the age of 40 years and is associated with significant morbidity, mortality, and QoL impairment.18 It has been estimated that 202 million people worldwide have PAD.19 The purpose of this document is to provide a contemporary guideline for diagnosis and management of patients with lower extremity PAD. This document supersedes recommendations related to lower extremity PAD in the “ACC/AHA 2005 Guidelines for the Management of Patients With Peripheral Arterial Disease”9 and the “2011 ACCF/AHA Focused Update of the Guideline for the Management of Patients With Peripheral Artery Disease.”10 The scope of this guideline is limited to atherosclerotic disease of the lower extremity arteries (PAD) and includes disease of the aortoiliac, femoropopliteal, and infrapopliteal arterial segments. It does not address nonatherosclerotic causes of lower extremity arterial disease, such as vasculitis, fibromuscular dysplasia, physiological entrapment syndromes, cystic adventitial disease, and other entities. Future guidelines will address aneurysmal disease of the abdominal aorta and lower extremity arteries and diseases of the renal and mesenteric arteries.

In developing the “2016 AHA/ACC Guideline on the Management of Patients With Lower Extremity Peripheral Artery Disease,” the writing committee reviewed the evidence to support recommendations in the relevant ACC/AHA guidelines noted in Table 2 and affirms the ongoing validity of the related recommendations, thus obviating the need to repeat existing guideline recommendations in the current guideline. Table 2 also contains a list of other statements that may be of interest to the reader. Table 3 includes definitions for PAD key terms used throughout the guideline.

### Table 3. Definition of PAD Key Terms

<table>
<thead>
<tr>
<th>Term</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>Claudication</td>
<td>Fatigue, discomfort, cramping, or pain of vascular origin in the muscles of the lower extremities that is consistently induced by exercise and consistently relieved by rest (within 10 min).</td>
</tr>
<tr>
<td>Acute limb ischemia (ALI)</td>
<td>Acute (&lt;2 wk), severe hypoperfusion of the limb characterized by these features: pain, pallor, pulselessness, poikilothermia (cold), paresthesias, and paralysis. One of these categories of ALI is assigned (Section 10):</td>
</tr>
<tr>
<td></td>
<td>I. Viable—Limb is not immediately threatened; no sensory loss; no muscle weakness; audible arterial and venous Doppler.</td>
</tr>
<tr>
<td></td>
<td>II. Threatened—Mild-to-moderate sensory or motor loss; inaudible arterial Doppler; audible venous Doppler; may be further divided into Ila (marginally threatened) or Iib (immediately threatened).</td>
</tr>
<tr>
<td></td>
<td>III. Irreversible—Major tissue loss or permanent nerve damage inevitable; profound sensory loss, anesthetic; profound muscle weakness or paralysis (rigor); inaudible arterial and venous Doppler.</td>
</tr>
<tr>
<td>Tissue loss</td>
<td>Type of tissue loss:</td>
</tr>
<tr>
<td></td>
<td>Minor—nonhealing ulcer, focal gangrene with diffuse pedal ischemia.</td>
</tr>
<tr>
<td></td>
<td>Major—extending above transmetatarsal level; functional foot no longer salvageable.</td>
</tr>
<tr>
<td>Critical limb ischemia (CLI)</td>
<td>A condition characterized by chronic (≥2 wk) ischemic rest pain, nonhealing wound/ulcers, or gangrene in 1 or both legs attributable to objectively proven arterial occlusive disease. The diagnosis of CLI is a constellation of both symptoms and signs. Arterial disease can be proved objectively with ABI, TBI, TcPO₂, or skin perfusion pressure. Supplementary parameters, such as absolute ankle and toe pressures and pulse volume recordings, may also be used to assess for significant arterial occlusive disease. However, a very low ABI or TBI does not necessarily mean the patient has CLI. The term CLI implies chronicity and is to be distinguished from ALI.</td>
</tr>
<tr>
<td>In-line blood flow</td>
<td>Direct arterial flow to the foot, excluding collaterals.</td>
</tr>
<tr>
<td>Functional status</td>
<td>Patient’s ability to perform normal daily activities required to meet basic needs, fulfill usual roles, and maintain health and well-being. Walking ability is a component of functional status.</td>
</tr>
<tr>
<td>Nonviable limb</td>
<td>Condition of extremity (or portion of extremity) in which loss of motor function, neurological function, and tissue integrity cannot be restored with treatment.</td>
</tr>
<tr>
<td>Salvageable limb</td>
<td>Condition of extremity with potential to secure viability and preserve motor function to the weight-bearing portion of the foot if treated.</td>
</tr>
<tr>
<td>Structured exercise program</td>
<td>Planned program that provides individualized recommendations for type, frequency, intensity, and duration of exercise. Program provides recommendations for exercise progression to assure that the body is consistently challenged to increase exercise intensity and levels as functional status improves over time. There are 2 types of structured exercise program for patients with PAD:</td>
</tr>
<tr>
<td></td>
<td>1. Supervised exercise program</td>
</tr>
<tr>
<td></td>
<td>2. Structured community- or home-based exercise program</td>
</tr>
<tr>
<td>Supervised exercise program</td>
<td>Structured exercise program that takes place in a hospital or outpatient facility in which intermittent walking exercise is used as the treatment modality. Program can be standalone or can be made available within a cardiac rehabilitation program. Program is directly supervised by qualified healthcare provider(s). Training is performed for a minimum of 30 to 45 min per session, in sessions performed at least 3 times/wk for a minimum of 12 wk. Patients may not initially achieve these targets, and a treatment goal is to progress to these levels over time. Training involves intermittent bouts of walking to moderate-to-maximum claudication, alternating with periods of rest. Warm-up and cool-down periods precede and follow each session of walking.</td>
</tr>
<tr>
<td>Structured community- or home-based exercise program</td>
<td>Structured exercise program that takes place in the personal setting of the patient rather than in a clinical setting. Program is self-directed with the guidance of healthcare providers who prescribe an exercise regimen similar to that of a supervised program. Patient counseling ensures that patients understand how to begin the program, how to maintain the program, and how to progress the difficulty of the walking (by increasing distance or speed). Program may incorporate behavioral change techniques, such as health coaching and/or use of activity monitors.</td>
</tr>
</tbody>
</table>

(Continued)
Table 3. Continued

<table>
<thead>
<tr>
<th>Term</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>Emergency versus urgent</td>
<td>An emergency procedure is one in which life or limb is threatened if the patient is not in the operating room or interventional suite and/or where there is time for no or very limited clinical evaluation, typically within &lt;6 h. An urgent procedure is one in which there may be time for a limited clinical evaluation, usually when life or limb is threatened if the patient is not in the operating room or interventional suite, typically between 6 and 24 h.</td>
</tr>
<tr>
<td>Interdisciplinary care team</td>
<td>A team of professionals representing different disciplines to assist in the evaluation and management of the patient with PAD. For the care of patients with CLI, the interdisciplinary care team should include individuals who are skilled in endovascular revascularization, surgical revascularization, wound healing therapies and foot surgery, and medical evaluation and care. Interdisciplinary care team members may include: Vascular medical and surgical specialists (ie, vascular medicine, vascular surgery, interventional radiology, interventional cardiology) Nurses Orthopedic surgeons and podiatrists Endocrinologists Internal medicine specialists Infectious disease specialists Radiology and vascular imaging specialists Physical medicine and rehabilitation clinicians Orthotics and prosthetics specialists Social workers Exercise physiologists Physical and occupational therapists Nutritionists/dieticians</td>
</tr>
<tr>
<td>Cardiovascular ischemic events</td>
<td>Acute coronary syndrome (acute MI, unstable angina), stroke, or cardiovascular death.</td>
</tr>
<tr>
<td>Limb-related events</td>
<td>Worsening claudication, new CLI, new lower extremity revascularization, or new ischemic amputation.</td>
</tr>
</tbody>
</table>

ABI indicates ankle-brachial index; ALI, acute limb ischemia; CLI, critical limb ischemia; MI, myocardial infarction; PAD, peripheral artery disease; TBI, toe-brachial index; and TcPO2, transcutaneous oxygen pressure.

2. CLINICAL ASSESSMENT FOR PAD
Evaluating the patient for PAD begins with the clinical history, review of symptoms, and physical examination.

2.1. History and Physical Examination: Recommendations

<table>
<thead>

Patients at increased risk of PAD (Table 4) should undergo vascular examination, including palpation of lower extremity pulses (ie, femoral, popliteal, dorsalis pedis, and posterior tibial), auscultation for femoral bruits, and inspection of the legs and feet.56,58,59

A thorough lower extremity vascular examination and careful inspection of the legs and feet are important components of the clinical assessment for PAD. To perform a thorough examination, legs and feet are examined with lower garments (pants/skirt, shoes, and socks) removed. Examination findings suggestive of PAD are shown in Table 5. Lower extremity pulses should be assessed and rated as follows: 0, absent; 1, diminished; 2, normal; or 3, bounding. Reproducibility of pulse assessment is better for detection of normal versus absent pulse than for normal versus diminished pulse.56 Absence of the dorsalis pedis pulse is less accurate for diagnosis of PAD than is absence of the posterior tibial pulse because the dorsalis pedis pulse can be absent on examination in a significant percentage of healthy patients.56,58 Abnormal physical findings, such as a pulse abnormality, require confirmation with the ankle-brachial index (ABI) to establish the diagnosis of PAD. Similarly, an entirely normal pulse examination and absence of bruits decreases the likelihood of confirmed PAD.56,58,59 Abnormal physical findings, such as multiple pulse abnormalities or bruits, increases the likelihood of confirmed PAD.56,58,59 The presence of nonhealing lower extremity wounds may be a sign of CLI. Findings of cool or discolored skin and delayed capillary refill are not reliable for PAD diagnosis.56 To confirm the diagnosis of PAD, abnormal physical examination findings must be confirmed with diagnostic testing (Section 3), generally with the ABI as the initial test.

Patients with PAD should undergo noninvasive blood pressure measurement in both arms at least once during the initial assessment.60–62

An inter-arm blood pressure difference of >15 to 20 mm Hg is abnormal and suggestive of subclavian (or innominate) artery stenosis. Patients with PAD are at increased risk of subclavian artery stenosis.60–62 Measuring blood pressure in both arms identifies the arm with the highest systolic pressure, a requirement for accurate measurement of the ABI.27 Identification of unequal blood pressures in the arms also allows for more accurate measurement of blood pressure in the treatment of hypertension (ie, blood pressure is taken at the arm with higher measurements). Although a difference in arm systolic pressures of >15 to 20 mm Hg suggests subclavian (or innominate) artery stenosis, in the absence of symptoms (eg, arm claudication or symptoms of vertebral artery steal), no further imaging or intervention is warranted.

### Table 4. Patients at Increased Risk of PAD

| Age ≥65 y | Age 50–64 y, with risk factors for atherosclerosis (eg, diabetes mellitus, history of smoking, hyperlipidemia, hypertension) or family history of PAD63 |
| Age <50 y, with diabetes mellitus and 1 additional risk factor for atherosclerosis |
| Individuals with known atherosclerotic disease in another vascular bed (eg, coronary, carotid, subclavian, renal, mesenteric artery stenosis, or AAA) |

AAA indicates abdominal aortic aneurysm; PAD, peripheral artery disease.

### Table 5. History and/or Physical Examination Findings Suggestive of PAD

| History |
| Claudication |
| Other non–joint-related exertional lower extremity symptoms (not typical of claudication) |
| Impaired walking function |
| Ischemic rest pain |
| Physical Examination |
| Abnormal lower extremity pulse examination |
| Vascular bruit |
| Nonhealing lower extremity wound |
| Lower extremity gangrene |
| Other suggestive lower extremity physical findings (eg, elevation pallor/dependent rubor) |

PAD indicates peripheral artery disease.
3. DIAGNOSTIC TESTING FOR THE PATIENT WITH SUSPECTED LOWER EXTREMITY PAD (CLAUDICATION OR CLI)

3.1. Resting ABI for Diagnosing PAD: Recommendations

**Recommendations for Resting ABI for Diagnosing PAD**

<table>
<thead>
<tr>
<th>COR</th>
<th>LOE</th>
<th>Recommendations</th>
</tr>
</thead>
<tbody>
<tr>
<td>I</td>
<td>B-NR</td>
<td>In patients with history or physical examination findings suggestive of PAD (Table 5), the resting ABI, with or without segmental pressures and waveforms, is recommended to establish the diagnosis.44-49</td>
</tr>
</tbody>
</table>

The resting ABI is obtained by measuring systolic blood pressures at the arms (brachial arteries) and ankles (dorsalis pedis and posterior tibial arteries) in the supine position by using a Doppler device. The ABI of each leg is calculated by dividing the higher of the dorsalis pedis or posterior tibial pressure by the higher of the right or left arm blood pressure.27 In patients with a history or physical examination suggestive of PAD, the ABI has good validity as a first-line test in the diagnosis of PAD, as shown by vascular imaging, with sensitivities ranging from 68% to 84% and specificities from 84% to 99%.64-69

Segmental lower extremity blood pressures and Doppler or plethysmographic waveforms (pulse volume recordings) can be used to localize anatomic segments of disease (eg, aortoiliac, femoropopliteal, infrapopliteal).24,70,71

See Online Data Supplement 4.

| I   | C-LD | Resting ABI results should be reported as abnormal (ABI ≤0.90), borderline (ABI 0.91–0.99), normal (1.00–1.40), or noncompressible (ABI >1.40).27,67-69,72 |

See Online Data Supplement 4.

| IIa | B-NR | In patients at increased risk of PAD (Table 4) but without history or physical examination findings suggestive of PAD, measurement of the resting ABI is reasonable.54,65,76-97 |

See Online Data Supplements 3 and 4.

| I   | B-NR | The ABI test is noninvasive, is simple to perform, and has minimal risks, making it suitable for use in asymptomatic individuals. Previous studies have demonstrated a significant prevalence of abnormal resting ABI among asymptomatic patients with risk factors for PAD.95,79,80 A significant body of evidence demonstrates that patients with an abnormal ABI who are asymptomatic have poorer cardiovascular morbidity and mortality outcomes than do patients with normal ABI.79-80 While there is no conclusive evidence that aspirin treatment changes cardiovascular or limb outcomes in this population, in 1 cohort study of 5480 patients with asymptomatic PAD, statin treatment improved cardiovascular outcomes.73-76 |

There is also evidence that asymptomatic patients with a low resting ABI have a poorer functional status and a more rapid rate of functional decline than do patients with a normal ABI.54,65,75-79 Although physical activity has been shown to be associated with improvement in functional status in patients with asymptomatic PAD,96 the benefit of ABI testing to identify asymptomatic patients who are at increased risk of functional decline and may benefit from structured exercise programs remains to be determined. |

See Online Data Supplement 4.

| III: No Benefit | B-NR | In patients not at increased risk of PAD (Table 4) and without history or physical examination findings suggestive of PAD (Table 5), the ABI is not recommended.95,96 |

| II: No Benefit | B-NR | The prevalence of PAD among individuals without risk factors for atherosclerosis and who are <50 years of age is low. Data from population-based cohort studies have demonstrated a low prevalence (approximately 1%) of abnormal resting ABI among individuals <50 years of age.95,96 In the NHANES (National Health and Nutrition Study), approximately 95% of participants with an abnormal resting ABI had at least 1 risk factor for atherosclerosis.95 The yield of ABI testing among younger, asymptomatic individuals without risk factors for atherosclerosis is low, and these patients should not be routinely tested for PAD.95,96 |

See Online Data Supplement 4.

3.2. Physiological Testing: Recommendations

**Recommendations for Physiological Testing**

<table>
<thead>
<tr>
<th>COR</th>
<th>LOE</th>
<th>Recommendations</th>
</tr>
</thead>
<tbody>
<tr>
<td>I</td>
<td>B-NR</td>
<td>Toe–brachial index (TBI) should be measured to diagnose patients with suspected PAD when the ABI is greater than 1.40.72,99-102</td>
</tr>
</tbody>
</table>

TBI is a noninvasive test that is useful to evaluate for PAD in patients with noncompressible arteries, which cause an artificial elevation of the ABI.99,100,102,103 A TBI ≤0.70 is abnormal and diagnostic of PAD because the digital arteries are rarely noncompressible.98-100,104,105 Patients with longstanding diabetes mellitus72,73 or advanced chronic kidney disease106 have a high incidence of noncompressible arteries. Therefore, TBI assessment allows for the diagnosis of PAD in these patients with noncompressible arteries who have history or physical examination findings suggestive of PAD (Figure 1).

PAD indicates peripheral artery disease.

Figure 1. Diagnostic Testing for Suspected PAD.

Colors correspond to Class of Recommendation in Table 1. ABI indicates ankle-brachial index; CLI, critical limb ischemia; CTA, computed tomography angiography; GDMT, guideline-directed management and therapy; MRA, magnetic resonance angiography; PAD, peripheral artery disease; and TBI, toe-brachial index.
3.3. Imaging for Anatomic Assessment: Recommendations

**Figure 2. Diagnostic Testing for Suspected CLI.**
Colors correspond to Class of Recommendation in Table 1. *Order based on expert consensus. †TBI with waveforms, if not already performed. ABI indicates ankle-brachial index; CLI, critical limb ischemia; CTA, computed tomography angiography; MRA, magnetic resonance angiography; TcPO2, transcutaneous oxygen pressure; and TBI, toe-brachial index.

### Recommendations for Imaging for Anatomic Assessment

<table>
<thead>
<tr>
<th>COR</th>
<th>LOE</th>
<th>Recommendations</th>
</tr>
</thead>
<tbody>
<tr>
<td>I</td>
<td>B-NR</td>
<td>Duplex ultrasound, computed tomography angiography (CTA), or magnetic resonance angiography (MRA) of the lower extremities is useful to diagnose anatomic location and severity of stenosis for patients with symptomatic PAD in whom revascularization is considered.118,120–122</td>
</tr>
</tbody>
</table>

For symptomatic patients in whom ABI/TBI confirms PAD and in whom revascularization is considered, additional imaging with duplex ultrasonography, CTA, or MRA is useful to develop an individualized treatment plan, including assistance in selection of vascular access sites, identification of significant lesions, and determination of the feasibility of and modality for invasive treatment. All 3 of these noninvasive imaging methods have good sensitivity and specificity as compared with invasive angiography.118,120–122 Renal function does not affect the safety of duplex ultrasonography, although duplex offers lower spatial resolution than CTA and MRA in the setting of arterial calcification. The tomographic data from CTA and MRA afford 3-dimensional reconstruction of the vessels examined. The iodinated contrast used in CTA confers risk of contrast-induced nephropathy and (rarely) severe allergic reaction.133,134 CTA uses ionizing radiation. MRA does not use ionizing radiation; however, gadolinium contrast used frequently in MRA studies confers risk of nephrogenic systemic sclerosis for patients with advanced renal dysfunction and is therefore contraindicated in this population.125 The choice of the examination should be determined in an individualized approach to the anatomic assessment for each patient, including risk–benefit assessment of each study type. If these noninvasive tests are nondiagnostic, then invasive angiography may be required to delineate anatomy and plan revascularization.
4. SCREENING FOR ATHEROSCLEROTIC DISEASE IN OTHER VASCULAR BEDS FOR THE PATIENT WITH PAD

4.1. Abdominal Aortic Aneurysm: Recommendation

**Recommendation for Abdominal Aortic Aneurysm**

<table>

**Recommendations for Imaging for Anatomic Assessment (Continued)**

<table>
<thead>
<tr>
<th>COR</th>
<th>LOE</th>
<th>Recommendations</th>
</tr>
</thead>
<tbody>
<tr>
<td>I</td>
<td>C-EO</td>
<td>Invasive angiography is useful for patients with CLI in whom revascularization is considered.</td>
</tr>
<tr>
<td></td>
<td>N/A</td>
<td>By definition, CLI results from extensive PAD that limits tissue perfusion. Because timely diagnosis and treatment are essential to preserve tissue viability in CLI, it is often most effective and expeditious to pursue invasive angiography with endovascular revascularization directly, without delay and potential risk of additional noninvasive imaging.</td>
</tr>
<tr>
<td>Ila</td>
<td>C-EO</td>
<td>Invasive angiography is reasonable for patients with lifestyle-limiting claudication with an inadequate response to GDMT for whom revascularization is considered.</td>
</tr>
<tr>
<td></td>
<td>N/A</td>
<td>For patients with lifestyle-limiting claudication despite GDMT (including structured exercise therapy) for whom revascularization is being considered, proceeding directly to invasive angiography for anatomic assessment and to determine revascularization strategy is reasonable. In certain clinical settings, noninvasive imaging studies for anatomic assessment (ie, duplex ultrasound, CTA, or MRA) may not be available because of lack of local resources or expertise. In addition, there are clinical scenarios in which noninvasive studies for anatomic assessment may be perceived to confer greater risk to the patient than invasive angiography (eg, patient with advanced chronic kidney disease for whom contrast dose for invasive angiography would be lower than that required for CTA).</td>
</tr>
<tr>
<td>III: Harm</td>
<td>B-R</td>
<td>Invasive and noninvasive angiography (ie, CTA, MRA) should not be performed for the anatomic assessment of patients with asymptomatic PAD.123,124,126</td>
</tr>
<tr>
<td></td>
<td>N/A</td>
<td>Angiography, either noninvasive or invasive, should not be performed for the anatomic assessment of patients with PAD without leg symptoms because delineation of anatomy will not change treatment for this population. This lack of benefit occurs in the setting of risk of contrast-induced nephropathy, patient discomfort, and allergic reactions.123,124,126 This recommendation does not address assessment of lower extremity aneurysmal disease or nonatherosclerotic causes of arterial disease, which is beyond the scope of this document.</td>
</tr>
</tbody>
</table>

4.2. Screening for Asymptomatic Atherosclerosis in Other Arterial Beds (Coronary, Carotid, and Renal Arteries)

The prevalence of atherosclerosis in the coronary, carotid, and renal arteries is higher in patients with PAD than in those without PAD.128,130–135 However, intensive atherosclerosis risk factor modification in patients with PAD is justified regardless of the presence of disease in other arterial beds. Thus, the only justification for screening for disease in other arterial beds is if revascularization results in a reduced risk of myocardial infarction (MI), stroke, or death, and this has never been shown. Currently, there is no evidence to demonstrate that screening all patients with PAD for asymptomatic atherosclerosis in other arterial beds improves clinical outcome. Intensive treatment of risk factors through GDMT is the principle method for preventing adverse cardiovascular ischemic events from asymptomatic disease in other arterial beds.

5. MEDICAL THERAPY FOR THE PATIENT WITH PAD

Patients with PAD should receive a comprehensive program of GDMT, including structured exercise and
lifestyle modification, to reduce cardiovascular ischemic events and improve functional status. Smoking cessation is a vital component of care for patients with PAD who continue to smoke. A guideline-based program of pharmacotherapy to reduce cardiovascular ischemic events and limb-related events should be prescribed for each patient with PAD and is customized to individual risk factors, such as whether the patient also has diabetes mellitus. Previous studies have demonstrated that patients with PAD are less likely to receive GDMT than are patients with other forms of cardiovascular disease, including coronary artery disease (CAD).\textsuperscript{136–138}

## 5.1. Antiplatelet Agents: Recommendations

### Recommendations for Antiplatelet Agents

<table>
<thead>
<tr>
<th>COR</th>
<th>LOE</th>
<th>Recommendations</th>
</tr>
</thead>
<tbody>
<tr>
<td>I</td>
<td>A</td>
<td><strong>Antiplatelet therapy with aspirin alone (range 75–325 mg per day) or clopidogrel alone (75 mg per day) is recommended to reduce MI, stroke, and vascular death in patients with symptomatic PAD.</strong>\textsuperscript{139–142}</td>
</tr>
<tr>
<td></td>
<td></td>
<td>The effect of antiplatelet therapy on cardiovascular events has been systematically reviewed by the Antithrombotic Trialists’ Collaboration.\textsuperscript{139} Of note, this meta-analysis included studies of antiplatelet agents other than aspirin or clopidogrel. Among patients with symptomatic PAD treated with antiplatelet therapy, there was a 22% odds reduction for cardiovascular events, including MI, stroke, or vascular death.\textsuperscript{139} Symptomatic patients with lower extremity PAD included both those with claudication and those with prior lower extremity revascularization. The Antithrombotic Trialists’ Collaboration meta-analysis also compared the efficacy of different doses of aspirin.\textsuperscript{139} The proportional reduction in vascular events was 32% with 75 to 150 mg daily, 26% with 160 to 325 mg daily, and 19% with 500 to 1500 mg daily, whereas there was a significantly smaller (13%) reduction in cardiovascular events in patients being treated with &lt;75 mg of aspirin per day.\textsuperscript{139} CLIPS (Critical Leg Ischaemia Prevention Study) demonstrated a benefit of aspirin (100 mg daily) compared with placebo in preventing vascular events, but the study was too small to derive meaningful conclusions.\textsuperscript{140} A meta-analysis of trials of aspirin (alone or in combination with dipyridamole) for prevention of cardiovascular events in patients with PAD found a non–statistically significant reduction in the primary endpoint of cardiovascular death, MI, and stroke and a statistically significant reduction in the secondary endpoint of nonfatal stroke with aspirin versus placebo.\textsuperscript{141} The CAPRIE (Clopidogrel Versus Aspirin in Patients at Risk of Ischemic Events) trial demonstrated a benefit of clopidogrel as compared with aspirin in cardiovascular risk reduction and bleeding events in a population of patients with symptomatic atherosclerotic vascular disease, including a subgroup of patients with symptomatic PAD.\textsuperscript{142}</td>
</tr>
<tr>
<td></td>
<td></td>
<td>In asymptomatic patients with PAD (ABI ≤0.90), antiplatelet therapy is reasonable to reduce the risk of MI, stroke, or vascular death.\textsuperscript{143}</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Patients with PAD (ie, ABI ≤0.90) who do not have claudication may have leg symptoms atypical for claudication or may be too functionally limited to allow for adequate leg symptom assessment. Patients with PAD without claudication are at increased cardiovascular risk.\textsuperscript{79} Subgroup analysis in a trial evaluating asymptomatic patients did not show an effect of aspirin in patients with an abnormally low ABI (&lt;0.80 or ≤0.90).\textsuperscript{79} However, the trial was not powered to analyze subgroups, and the uncertainty of the result does not rule out the possibility that aspirin could provide benefit in such patients, especially in those at increased risk of cardiovascular events. Another trial that included asymptomatic patients was too small to derive meaningful conclusions.\textsuperscript{140}</td>
</tr>
<tr>
<td></td>
<td></td>
<td>In asymptomatic patients with borderline ABI (0.91–0.99), the usefulness of antiplatelet therapy to reduce the risk of MI, stroke, or vascular death is uncertain.\textsuperscript{76,79}</td>
</tr>
<tr>
<td></td>
<td></td>
<td>In asymptomatic patients with an abnormal or borderline ABI, 2 RCTs found that aspirin had no effect in reducing cardiovascular events\textsuperscript{76,79} and might increase bleeding.\textsuperscript{76} However, the trials were not powered to examine patients with borderline ABI separately. Given that cardiovascular risk is lower in patients with borderline ABI than in those with abnormal ABI,\textsuperscript{80} it would be unlikely that aspirin would have a meaningful effect in this subgroup when there was no evidence of an effect in the total trial populations.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>The effectiveness of dual antiplatelet therapy (DAPT) (aspirin and clopidogrel) to reduce the risk of cardiovascular ischemic events in patients with symptomatic PAD is not well established.\textsuperscript{143,144}</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Based on findings from a subset of patients with PAD in the CHARISMA (Clopidogrel for High Atherothrombotic Risk and Ischemic Stabilization, Management, and Avoidance) trial, DAPT with aspirin plus clopidogrel may be considered for patients with PAD at particularly high risk of cardiovascular ischemic events who are not at high risk of bleeding.\textsuperscript{143,144} Currently, there are sparse data on newer P2Y\textsubscript{12} antagonists for PAD. There is uncertainty about the net benefit of long-term DAPT for patients with PAD—specifically the balance of risks of cardiovascular ischemic events versus major bleeding. Additional clinical trials are needed in the population with PAD. Refer to the DAPT guideline focused update for DAPT recommendations specifically for CAD.\textsuperscript{20}</td>
</tr>
</tbody>
</table>

See Online Data Supplement 13.
Recommendations for Antiplatelet Agents (Continued)

<table>
<thead>
<tr>
<th>COR</th>
<th>LOE</th>
<th>Recommendations</th>
</tr>
</thead>
<tbody>
<tr>
<td>IIb</td>
<td>C-LD</td>
<td>DAPT (aspirin and clopidogrel) may be reasonable to reduce the risk of limb-related events in patients with symptomatic PAD after lower extremity revascularization.146–148</td>
</tr>
</tbody>
</table>

See Online Data Supplements 13 and 14.

IIb B-R The overall clinical benefit of vorapaxar added to existing antiplatelet therapy in patients with symptomatic PAD is uncertain.149–152

See Online Data Supplement 13.

This novel antagonist of protease-activated receptor-1 added to existing antiplatelet therapy reduced the risk of cardiovascular ischemic events in patients with atherosclerosis who were receiving standard therapy in an RCT.150,151 However, it also increased the risk of moderate or severe bleeding. Although the cardiovascular benefit was not demonstrated in the subgroup with symptomatic PAD, there was a reduction in limb-related events with vorapaxar, specifically in acute limb ischemia (ALI) and peripheral revascularization.149,152 More than half of ALI events in the PAD subset were due to thrombosis of lower extremity bypass grafts.149 Unfortunately, the benefit in limb events in patients with PAD was accompanied by an increased risk of bleeding.149,152 Therefore, the overall clinical benefit of vorapaxar in patients with PAD is uncertain.

5.2. Statin Agents: Recommendation

<table>
<thead>
<tr>
<th>Recommendation for Statin Agents</th>
</tr>
</thead>
<tbody>
<tr>
<td>COR</td>
</tr>
<tr>
<td>-----</td>
</tr>
<tr>
<td>I</td>
</tr>
</tbody>
</table>

Statin therapy improves both cardiovascular and limb outcomes in patients with PAD.157 In a subgroup of 6748 patients with PAD in the HPS (Heart Protection Study), simvastatin 40 mg daily reduced the rate of first major vascular event by 22% relative to placebo.156

In a multinational registry, statin use among patients with PAD reduced 4-year adverse limb-related events (ie, worsening claudication, new CLI, new lower extremity revascularization, new ischemic amputation) compared with no statin.150 Use of simvastin in the HPS reduced relative risk of peripheral vascular events (including noncoronary revascularization, aneurysm repair, major amputation, or PAD death) compared with placebo.155 In Medicare patients undergoing lower extremity revascularization, 1-year limb salvage rates were improved among those receiving statin medication.154 In a multicenter RCT, use of atorvastatin 80 mg daily improved pain-free walking time and community-based walking at 12 months compared with placebo.156 In 1 cohort study of 5480 patients with asymptomatic PAD, statin treatment improved cardiovascular outcomes.96 Guidelines for dosing of statin medications have been previously published.24

5.3. Antihypertensive Agents: Recommendations

<table>
<thead>
<tr>
<th>Recommendations for Antihypertensive Agents</th>
</tr>
</thead>
<tbody>
<tr>
<td>COR</td>
</tr>
<tr>
<td>-----</td>
</tr>
<tr>
<td>I</td>
</tr>
</tbody>
</table>

Treatment of elevated blood pressure is indicated to lower the risk of cardiovascular events.152 Target blood pressure and selection of antihypertensive therapy should be consistent with current published guidelines for hypertension management. Concerns have been raised that antihypertensive therapy may reduce limb perfusion. However, multiple studies have demonstrated that blood pressure treatment, including the use of beta blockers, does not worsen claudication symptoms or impair functional status in patients with PAD.153–155 There is no evidence that one class of antihypertensive medication or strategy is superior for blood pressure lowering in PAD.158,166,167 An updated multisocietal guideline on the management of high blood pressure is anticipated in 2017.
5.4. Smoking Cessation: Recommendations

**Recommendations for Smoking Cessation**

**COR** | **LOE** | **Recommendations**
--- | --- | ---
I | A | **Patients with PAD who smoke cigarettes or use other forms of tobacco should be advised at every visit to quit.**¹⁷⁰–¹⁷²

See Online Data Supplements 19 and 20.

- Tobacco use is a strong risk factor for the development and progression of PAD.¹⁷³,¹⁷⁴ Sparse evidence exists with regard to the association of novel tobacco product use, including electronic cigarettes, and PAD.¹⁷³ Observational studies suggest that smoking cessation is associated with lower rates of cardiovascular ischemic events, limb-related events, bypass graft failure, amputation, and death in patients with PAD.¹⁷²,¹⁷₆–¹⁷⁸ Clinician advice increases quit rates, which supports simple provider-based measures as a component of smoking cessation programs.¹²,¹⁷₁,¹⁷₉

- Coordinated smoking cessation interventions that include nonpharmacological and pharmacological approaches have the greatest efficacy. An RCT of a follow-up program and smoking cessation medications provided to hospitalized patients, including those with PAD, demonstrated a modest increase in quit rates.¹⁸¹ In an RCT of patients with PAD specifically, a comprehensive smoking cessation program combining counseling and pharmacological agents increased the rates of smoking cessation to 21.3%, compared with 6.8% with standard advice.¹⁸² Three pharmacological approaches (ie, varenicline, bupropion, and nicotine replacement therapy) used alone or in combination increased smoking cessation rates.¹⁷₀,¹⁷₀–¹⁸₂ Two meta-analyses of RCTs of smoking cessation medications showed no evidence of increased cardiovascular event rates with nicotine replacement, bupropion, or varenicline.¹⁸₃,¹⁸₄ Sparse data suggest that electronic cigarettes have no benefit on smoking cessation rates.¹⁷⁹

- Patients with PAD who smoke cigarettes should be assisted in developing a plan for quitting that includes pharmacotherapy (ie, varenicline, bupropion, and/or nicotine replacement therapy) and/or referral to a smoking cessation program.¹⁷₀,¹⁸₀–¹₈₂

See Online Data Supplements 19 and 20.

- Patients with PAD should avoid exposure to environmental tobacco smoke at work, at home, and in public places.¹⁸⁵,¹⁸₆

See Online Data Supplement 20.

- Passive smoke exposure has been associated with the development of PAD.¹⁸⁶ Observational studies have shown lower cardiovascular and cerebrovascular event rates in the general population after enactment of smoke-free legislation.¹⁸₂ The effects of avoidance of passive smoke exposure on limb-related events are not known.

5.5. Glycemic Control: Recommendations

**Recommendations for Glycemic Control**

**COR** | **LOE** | **Recommendations**
--- | --- | ---
I | C-E0 | **Management of diabetes mellitus in the patient with PAD should be coordinated between members of the healthcare team.**

N/A

Diabetes mellitus is an important risk factor for the development of PAD.¹⁸⁷ Furthermore, the presence of diabetes mellitus increases the risk of adverse outcomes among patients with PAD, including progression to CLI, amputation, and death.¹⁴⁸,¹⁴⁹ A comprehensive care plan for patients with PAD and diabetes mellitus is important and may include diet and weight management, pharmacotherapy for glycemic control and management of other cardiovascular risk factors, and foot care and ulcer prevention.¹⁵⁰ Guidelines for glycemic control among patients with diabetes mellitus and atherosclerotic vascular disease have been previously published.¹⁵¹,¹⁵² Regular follow-up with and communication among the patient’s healthcare providers, including vascular specialists and diabetes care providers (eg, primary care physicians, endocrinologists) constitute an important component of care for patients with PAD and diabetes mellitus.
### 5.6. Oral Anticoagulation: Recommendations

#### Recommendations for Oral Anticoagulation

<table>
<thead>
<tr>
<th>COR</th>
<th>LOE</th>
<th>Recommendations</th>
</tr>
</thead>
<tbody>
<tr>
<td>IIb</td>
<td>B-R</td>
<td><strong>The usefulness of anticoagulation to improve patency after lower extremity autogenous vein or prosthetic bypass is uncertain.</strong>[^193-195]</td>
</tr>
</tbody>
</table>

Two RCTs evaluating the effectiveness of oral anticoagulation (warfarin) in improving lower extremity bypass patency demonstrated improved patency among the subgroup of patients with autogenous vein bypass grafts.[^193,194] However, a Cochrane systematic review showed no patency benefit with the use of anticoagulation compared with antiplatelet therapy.[^195] All RCTs and observational studies evaluating the effect of anticoagulants on bypass patency demonstrated increased bleeding complications associated with anticoagulant use. One RCT evaluating the effectiveness of oral anticoagulation (warfarin) in addition to aspirin in improving lower extremity bypass patency demonstrated improved patency in a subgroup of patients with 6-mm polytetrafluoroethylene (known as PTFE) bypass graft.[^196] Randomization to anticoagulation plus aspirin was associated with increased risk of death and major hemorrhage versus aspirin alone.

#### Recommendation for Cilostazol

<tr>
<td><strong>COR</strong></td>
</tr>
<tr>
<td>III: No Benefit</td>
</tr>
</tbody>
</table>

See Online Data Supplement 27.

In a Cochrane review of 5 studies with 260 participants, chelation therapy showed no significant difference in symptoms (maximal and pain-free walking distance) compared with placebo.204

5.10. Homocysteine Lowering: Recommendation

<table>
<thead>
<tr>
<th>Recommendation for Homocysteine Lowering</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>COR</strong></td>
</tr>
<tr>
<td>III: No Benefit</td>
</tr>
</tbody>
</table>

See Online Data Supplements 28 and 29.

Although patients with PAD have been shown to have increased plasma homocysteine levels compared with patients without PAD, there is no evidence that B-complex vitamin supplementation improves clinical outcomes in patients with PAD.207 The HOPE-2 trial randomized 5522 patients with atherosclerotic vascular disease, including symptomatic PAD, or diabetes mellitus with additional risk factors to receive folic acid/vitamin B6/vitamin B12 or placebo.205,206 Despite lowering of homocysteine levels in the vitamin supplementation arm, there was no improvement in the primary endpoint of cardiovascular death, MI, or stroke.

5.11. Influenza Vaccination: Recommendation

<table>
<thead>
<tr>
<th>Recommendation for Influenza Vaccination</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>COR</strong></td>
</tr>
<tr>
<td>I</td>
</tr>
</tbody>
</table>

See Online Data Supplements 30 and 31.

Observational studies have demonstrated reduced cardiovascular event rates among patients with cardiovascular disease who have received an influenza vaccination.208 Two RCTs that enrolled patients with CAD demonstrated a benefit of an influenza vaccination on the prevention of cardiovascular events, particularly coronary ischemic events.206,209 Although these trials did not specifically enroll participants with PAD, a majority of patients with PAD also have CAD.20 On the basis of this evidence, an annual influenza vaccination is recommended as a component of medical therapy for patients with PAD.

6. STRUCTURED EXERCISE THERAPY: RECOMMENDATIONS

Structured exercise therapy is an important element of care for the patient with PAD. Components of structured exercise programs for PAD are outlined in Table 8.
### Recommendations for Structured Exercise Therapy

<table>
<thead>
<tr>
<th>COR</th>
<th>LOE</th>
<th>Recommendations</th>
</tr>
</thead>
<tbody>
<tr>
<td>I</td>
<td>A</td>
<td>**In patients with claudication, a supervised exercise program is recommended to improve functional status and QoL and to reduce leg symptoms.**36–38,40–46,210,211</td>
</tr>
</tbody>
</table>

The data supporting the efficacy of supervised exercise training as an initial treatment for claudication continue to develop and remain convincing, building on many earlier RCTs.50–46,210,211 Trials with long-term follow-up from 18 months37,38 to 7 years36 have demonstrated a persistent benefit of supervised exercise in patients with claudication. Data also support a benefit of supervised exercise for patients with symptomatic PAD and diabetes mellitus.212 The risk–benefit ratio for supervised exercise in PAD is favorable, with an excellent safety profile in patients screened for absolute contraindications to exercise such as exercise-limiting cardiovascular disease, amputation or wheelchair confinement, and other major comorbidities that would preclude exercise.36,38,40,215–218 Despite the health benefits associated with supervised exercise in patients with PAD, initiating and maintaining a high level of adherence remain challenging. Frequent contact with patients both when performing exercise in the supervised setting and at home has been somewhat effective in promoting retention.35,38

| I   | B-R | A supervised exercise program should be discussed as a treatment option for claudication before possible revascularization.36–38 |

The CLEVER (Claudication: Exercise Versus Endoluminal Revascularization) trial randomized patients with symptomatic aortoiliac PAD and showed comparable benefits for supervised exercise and stent revascularization at 6 and 18 months, with each therapy being superior to optimal medical care.35,38 Overall, the safety profile for supervised exercise was excellent. An RCT that compared 7-year effectiveness of supervised exercise or endovascular intervention in patients with stable claudication with iliac or femoropopliteal disease found no differences in improved walking and QoL outcomes.36 Although more secondary interventions occurred in the exercise group, the total number of interventions was greater in the endovascular revascularization group. Collectively, these studies provide strong support for offering patients a supervised exercise program for reducing claudication symptoms and for improving functional status and QoL.

| Ila | A   | **In patients with PAD, a structured community- or home-based exercise program with behavioral change techniques can be beneficial to improve walking ability and functional status.**40,83,94,213 |

Unstructured community-based or home-based walking programs that consist of providing general recommendations to patients with claudication to simply walk more are not efficacious.10 Studies supporting structured community- or home-based programs for patients with symptomatic PAD (claudication and/or leg symptoms atypical for claudication) are more recent than studies supporting supervised exercise programs, and have provided strong evidence in support of the community- or home-based approach.17,94,83,93,84,213 For example, the GOALS (Group Oriented Arterial Leg Study) trial54 included patients with confirmed PAD with and without claudication (atypical lower extremity symptoms or no symptoms) and showed increases in several parameters of functional status for both of these patient cohort subgroups, versus nonexercising controls, after 6 months,53 with improvement maintained at 12 months.34 As with supervised exercise programs, despite proven benefit, initiating and maintaining a high level of adherence to community- or home-based exercise programs remains challenging. Studies that have incorporated behavioral change techniques, such as health coaching and activity tracking used in supervised settings, appear to reduce attrition and promote higher levels of adherence, thereby improving functional and QoL outcomes, both short term and long term.43,83,94

| Ila | A   | **In patients with claudication, alternative strategies of exercise therapy, including upper-body ergometry, cycling, and pain-free or low-intensity walking that avoids moderate-to-maximum claudication while walking, can be beneficial to improve walking ability and functional status.**34,215,219,220 |

Protocols for exercise therapy for PAD traditionally have recommended intermittent walking bouts to moderate or higher pain levels interspersed with short periods of rest. Although these protocols are efficacious, intolerance of pain may lead to poor exercise adherence. An increasing number of studies have shown that modalities of exercise that avoid claudication or walking performed at intensities that are pain free or produce only mild levels of claudication can achieve health benefits comparable to walking at moderate or higher levels of claudication pain.39,41,215,219–221
7. MINIMIZING TISSUE LOSS IN PATIENTS WITH PAD: RECOMMENDATIONS

### Table 8. Structured Exercise Programs for PAD: Definitions

| Recommendations for Minimizing Tissue Loss in Patients With PAD |
|------------------|------------------|------------------|
| **COR** | **LOE** | **Recommendations** |
| **I** | **C-LD** | **Patients with PAD and diabetes mellitus should be counseled about self–foot examination and healthy foot behaviors.** [222,223] |
| **IIa** | **C-LD** | **Foot infections (infection of any of the structures distal to the malleoli) may include cellulitis, abscess, fasciitis, tenosynovitis, septic joint space infection, and osteomyelitis. Studies have investigated the accuracy of physical findings for identification of infection and determining infection severity and risk of amputation.** [224–226] Because of the consequences associated with untreated foot infection—especially in the presence of PAD—clinicians should maintain a high index of suspicion. [228] It is also recognized that the presence of diabetes mellitus with peripheral neuropathy and PAD may make the presentation of foot infection more subtle than in patients without these problems. Foot infection should be suspected if the patient presents with local pain or tenderness; periwound erythema; periwound edema, induration or fluctuance; pretibial edema; any discharge (especially purulent); foul odor; visible bone or a wound that probes-to-bone; or signs of a systemic inflammatory response (including temperature >38°C or <36°C, heart rate >90/min, respiratory rate >20/min or Paco₂ <32 mm Hg, white blood cell count >12,000 or <4000/mcL or >10% immature forms). [226] Probe-to-bone test is moderately predictive for osteomyelitis but is not pathognomonic. [227] |
| **IIa** | **C-LD** | **In patients with PAD and signs of foot infection, prompt referral to an interdisciplinary care team (Table 9) can be beneficial.** [228–230] |

</table>

Table 9. Interdisciplinary Care Team for PAD

A team of professionals representing different disciplines to assist in the evaluation and management of the patient with PAD. For the care of patients with CLI, the interdisciplinary care team should include individuals who are skilled in endovascular revascularization, surgical revascularization, wound healing therapies and foot surgery, and medical evaluation and care.

Interdisciplinary care team members may include:

- Vascular medical and surgical specialists (ie, vascular medicine, vascular surgery, interventional radiology, interventional cardiology)
- Nurses
- Orthopedic surgeons and podiatrists
- Endocrinologists
- Internal medicine specialists
- Infectious disease specialists
- Radiology and vascular imaging specialists
- Physical medicine and rehabilitation clinicians
- Orthotics and prosthetics specialists
- Social workers
- Exercise physiologists
- Physical and occupational therapists
- Nutritionists/dieticians

CLI indicates critical limb ischemia; and PAD, peripheral artery disease.

8. REVASCULARIZATION FOR CLAUDICATION

An individualized approach to revascularization for claudication is recommended for each patient to optimize outcome. Revascularization is but one component of care for the patient with claudication, as each patient should have a customized care plan that also includes medical therapy (Section 5), structured exercise therapy (Section 6), and care to minimize tissue loss (Section 7). If a strategy of revascularization for claudication is undertaken, the revascularization strategy should be evidence based and can include endovascular revascularization, surgery, or both.

Because of the variability of ischemic limb symptoms and impact of these symptoms on functional status and QoL, patients should be selected for revascularization on the basis of severity of their symptoms. Factors to consider include a significant disability as assessed by the patient, adequacy of response to medical and structured exercise therapy, status of comorbid conditions, and a favorable risk–benefit ratio. Patient preferences and goals of care are important considerations in the evaluation for revascularization. The revascularization strategy should have a reasonable likelihood of providing durable relief of symptoms. A general recommendation for revascularization as a treatment option for claudication is provided below followed by specific recommendations for endovascular (Section 8.1.1) and surgical (Section 8.1.2) procedures if a revascularization strategy is undertaken.

8.1. Revascularization for Claudication: Recommendation

<p>| Recommendation for Revascularization for Claudication |
|----------|-----|</p>
<table>
<thead>
<tr>
<th>COR</th>
<th>LOE</th>
<th>Recommendation</th>
</tr>
</thead>
<tbody>
<tr>
<td>IIa</td>
<td>A</td>
<td>Revascularization is a reasonable treatment option for the patient with lifestyle-limiting claudication with an inadequate response to GDMT.</td>
</tr>
</tbody>
</table>

A minority of patients with claudication (estimated at <10% to 15% over 5 years or more) will progress to CLI. Therefore, the role of revascularization in claudication is improvement in claudication symptoms and functional status, and consequently in QoL, rather than limb salvage. Revascularization is reasonable when the patient is being treated with GDMT (including structured exercise therapy) presents with persistent lifestyle-limiting claudication. Lifestyle-limiting claudication is defined by the patient rather than by any test. It includes impairment of activities of daily living and/or vocational and/or recreational activities due to claudication. There should be clear discussion with the patient about expected risks and benefits of revascularization, as well as discussion of the durability of proposed procedures.
### 8.1.1. Endovascular Revascularization for Claudication: Recommendations

Endovascular techniques to treat claudication include balloon dilation (angioplasty), stents, and atherectomy. These techniques continue to involve and now include covered stents, drug-eluting stents (DES), cutting balloons, and drug-coated balloons. The technique chosen for endovascular treatment is related to lesion characteristics (eg, anatomic location, lesion length, degree of calcification) and operator experience. Assessment of the appropriateness of specific endovascular techniques for specific lesions for the treatment of claudication is beyond the scope of this document.

Revascularization is performed on lesions that are deemed to be hemodynamically significant, and stenoses selected for endovascular treatment should have a reasonable likelihood of limiting perfusion to the distal limb. Stenoses of 50% to 75% diameter by angiography may not be hemodynamically significant, and resting or provoked intravascular pressure measurements may be used to determine whether lesions are significant. Multiple RCTs have compared endovascular procedures to various combinations of medical treatment with or without supervised or unsupervised exercise programs. These trials have used different endpoints and enrolled patients with anatomic disease distribution at different levels.

<th>COR</th>
<th>LOE</th>
<th>Recommendations</th>
</tr>
</thead>
<tbody>
<tr>
<td>III: Harm</td>
<td>B-NR</td>
<td>Surgical procedures should not be performed in patients with PAD solely to prevent progression to CLI.234–237,258–261</td>
</tr>
</tbody>
</table>

There are no data to support a practice paradigm of performing endovascular procedures on patients with PAD for the purpose of preventing progression of claudication symptoms to CLI. Reported rates of amputation or progression to CLI from prospective cohort studies of patients with claudication are <10% to 15% over 5 years or more, and increased mortality rate associated with claudication is usually the result of cardiovascular events rather than limb-related events.234–237,262 Similarly, there are no data to support revascularization in patients with asymptomatic PAD. Procedural risks include bleeding, renal failure from contrast-induced nephropathy, and the possibility of adverse limb outcomes.259–261 Therefore, the known risks of endovascular procedures outweigh any hypothetical benefit of preventing progression from asymptomatic PAD or claudication to CLI.

8.1.2. Surgical Revascularization for Claudication: Recommendations

<table>
<thead>
<tr>
<th>COR</th>
<th>LOE</th>
<th>Recommendations</th>
</tr>
</thead>
<tbody>
<tr>
<td>I</td>
<td>A</td>
<td>When surgical revascularization is performed, bypass to the popliteal artery with autogenous vein is recommended in preference to prosthetic graft material.263–271</td>
</tr>
</tbody>
</table>

The superficial femoral and proximal popliteal arteries are the most common anatomic sites of stenosis or occlusion among individuals with claudication. Femoral-popliteal bypass is therefore one of the most common surgical procedures for claudication and may be performed under general or regional anesthesia. The type of conduit and site of popliteal artery anastomosis (above versus below knee) are major determinants of outcomes associated with femoral-popliteal bypass. Systematic reviews and meta-analyses have identified a clear and consistent primary patency benefit for autogenous vein versus prosthetic grafts for popliteal artery bypass.270,271 Prosthetic grafts to the popliteal artery above the knee have reduced patency rates and increased rates of repeat intervention.283,286,288,272 Sparse evidence suggests a long-term patency advantage for Dacron over polytetrafluoroethylene (known as PTFE) graft for above-knee bypass,272 although this finding has not been consistently demonstrated in all RCTs.286,272,274

Ilia B-NR | Surgical procedures are reasonable as a revascularization option for patients with lifestyle-limiting claudication with inadequate response to GDMT, acceptable perioperative risk, and technical factors suggesting advantages over endovascular procedures.232,265,276–277 |

See Online Data Supplements 37 and 38.

Ilia B-NR | Femoral-tibial artery bypasses with prosthetic graft material should not be used for the treatment of claudication.287–289 |

See Online Data Supplement 37.

III: Harm B-R | Bypasses to the tibial arteries with prosthetic material for treatment of claudication should be avoided because of very high rates of graft failure and amputation.287–289 |

See Online Data Supplements 37 and 38.

III: Harm B-NR | Surgical procedures should not be performed in patients with PAD solely to prevent progression to CLI.234–237,262 |

See Online Data Supplements 37 and 38.

9. MANAGEMENT OF CLI

Patients with CLI are at increased risk of amputation and major cardiovascular ischemic events. Care of the patient with CLI includes evaluation for revascularization and wound healing therapies, with the objective to minimize tissue loss, completely heal wounds, and preserve a functional foot. Medical therapy to prevent cardiovascular ischemic events is also an important component of care for the patient with CLI (Section 5).
9.1. Revascularization for CLI: Recommendations

### Recommendation for Revascularization for CLI

<table>
<thead>
<tr>
<th>COR</th>
<th>LOE</th>
<th>Recommendation</th>
</tr>
</thead>
<tbody>
<tr>
<td>I</td>
<td>B-NR</td>
<td>In patients with CLI, revascularization should be performed when possible to minimize tissue loss.</td>
</tr>
</tbody>
</table>

See Online Data Supplement 39.

Patients with CLI are at high risk of major cardiovascular ischemic events, as well as nonhealing wounds and major amputation. In a systematic review of 13 studies of patients with CLI who did not receive revascularization, which included patients enrolled in medical and angiogenic therapy trials, there was a 22% all-cause mortality rate and a 22% rate of major amputation at a median follow-up of 12 months. The goal of surgical or endovascular revascularization is to provide in-line blood flow to the foot through at least 1 patent artery, which will help decrease ischemic pain and allow healing of any wounds, while preserving a functional limb. Multiple RCTs comparing contemporary surgical and endovascular treatment for patients with CLI are ongoing. Revascularization is not warranted in the setting of a nonviable limb.

| I   | C-EO | An evaluation for revascularization options should be performed by an interdisciplinary care team (Table 9) before amputation in the patient with CLI. |

Patients with CLI should be evaluated by an interdisciplinary care team. Before amputation, evaluation generally includes imaging for assessment of revascularization options (eg, duplex ultrasound, CTA, MRA, or catheter-based angiogram). The objective of this strategy is to minimize tissue loss and preserve a functional limb with revascularization.

### 9.1.1. Endovascular Revascularization for CLI: Recommendations

#### Recommendations for Endovascular Revascularization for CLI

<table>
<thead>
<tr>
<th>COR</th>
<th>LOE</th>
<th>Recommendations</th>
</tr>
</thead>
<tbody>
<tr>
<td>I</td>
<td>B-R</td>
<td>Endovascular procedures are recommended to establish in-line blood flow to the foot in patients with nonhealing wounds or gangrene.</td>
</tr>
</tbody>
</table>

See Online Data Supplement 39.

The technique chosen for endovascular treatment of CLI is related to anatomic location of lesions, lesion characteristics, and operator experience. Revascularization is performed on hemodynamically significant stenoses that are likely to be limiting blood flow to the limb. For stenoses of 50% to 75%, where the hemodynamic significance is unclear, intravascular pressure measurements may be used to determine hemodynamic significance. The BASIL (Bypass versus Angioplasty in Severe Ischemia of the Leg) RCT demonstrated that endovascular revascularization is an effective option for patients with CLI as compared with open surgery. The primary endpoint of amputation-free survival was the same in the endovascular and surgical arms. Of note, the endovascular arm used only PTA. Multiple RCTs comparing contemporary surgical and endovascular treatment for patients with CLI are ongoing.

| IIa | C-LD | A staged approach to endovascular procedures is reasonable in patients with ischemic rest pain.  |

For patients with multilevel disease who suffer from ischemic rest pain, in-flow lesions are generally addressed first. Depending on procedural characteristics, including contrast volume used, radiation exposure, and procedure time, out-flow lesions can be addressed in the same setting or at a later time if symptoms persist. This strategy for ischemic rest pain is distinct from the strategy recommended for CLI in the patient with a nonhealing wound or gangrene. In that scenario, restoration of direct in-line flow to the foot is essential for wound healing.

| IIa | B-R  | Evaluation of lesion characteristics can be useful in selecting the endovascular approach for CLI.  |

The lesion characteristics to consider include length, anatomic location, and extent of occlusive disease. For example, if an adequate angioplasty result can be achieved with PTA alone for short (<10 cm) stenoses in the femoropopliteal segment, then stent placement is not necessary. Presence of thrombosis or calcification at the lesion site will also affect the endovascular approach. In general, the advantages of DES and drug-coated balloons over PTA alone or bare-metal stents are more consistent in the femoropopliteal segment than for infrapopliteal interventions. However, these differences are mainly for patency, restenosis, and repeat-revascularization endpoints. Most studies were underpowered or did not examine other patient-oriented outcomes, such as amputation or wound healing in CLI. Endovascular techniques continue to evolve rapidly, and there has been limited literature comparing techniques with regard to clinically significant outcomes, such as amputation or wound healing.

<td></td>
<td></td>
<td>The management of patients with CLI and nonhealing wounds should include coordinated efforts for both revascularization and wound healing, because the risk of limb-threatening infections remains until complete wound healing is achieved. The structure and activities of interdisciplinary care teams for CLI may vary according to several factors, including the local availability of resources. Previous groups have described various combinations of activities of this team, which are in addition to revascularization and include functions such as wound care, infection management, orthotics, and prosthetics (see Online Data Supplement 34a for a complete list of functions). Coordination of these activities and some degree of organized team structure are recommended, as opposed to ad hoc or unstructured referrals among various specialty clinicians not involved in interdisciplinary care.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Ambulatory patients with PAD and nonhealing foot ulcers should be considered for efforts to prevent amputation. The components of this effort may include revascularization, offloading, treatment of infection, and wound care. The long-term outcome of the limb is excellent when complete wound healing can be achieved.332,333 Revascularization should be coordinated with the efforts of clinicians who manage foot infections, provide offloading, and achieve complete wound healing, either through medical therapy, surgical options, or a combination thereof. Coordinated and timely interdisciplinary care can achieve excellent limb outcomes for patients with PAD and nonhealing foot wounds.334,335-337</td>
</tr>
<tr>
<td>I</td>
<td>C-LD</td>
<td>In patients with CLI, wound care after revascularization should be performed with the goal of complete wound healing.338</td>
</tr>
<tr>
<td></td>
<td></td>
<td>A comprehensive plan for treatment of CLI must include a plan for achieving an intact skin surface on a functional foot. One study demonstrated a limb salvage rate of 100% at 3 years in a cohort of patients with CLI who achieved complete wound healing with endovascular revascularization and dedicated wound care.339 Before revascularization, the interdisciplinary care team should devise a plan to achieve the goal of complete wound healing. After successful revascularization, most patients with gangrene of the foot are evaluated for minor amputation with staged/delayed primary closure or surgical reconstruction when feasible.340-342 Negative-pressure wound therapy dressings are helpful to achieve wound healing after revascularization and minor (ie, digit or partial foot) amputation when primary or delayed secondary closure is not feasible.343,344 Spontaneous amputation, or autoamputation, of gangrenous digits should be reserved for palliation in patients without options for revascularization.345,346 Other evidence-based guidelines relevant to those with nonhealing foot wounds following revascularization cover the full spectrum of diabetic foot problems.347 or separately consider the management of infection,348-350 offloading,351 and wound care.352 To date, there are no RCTs or high-quality studies that have focused on wound healing adjuncts in limbs with severe PAD (eg, topical cytokine ointments, skin substitutes, cell-based therapies intended to optimize wound healing).</td>
</tr>

See Online Data Supplement 44.
10. MANAGEMENT OF ALI

ALI is one of the most treatable and potentially devastating presentations of PAD. Timely recognition of arterial occlusion as the cause of an ischemic, cold, painful leg is crucial to successful treatment. The writing committee has used a standard definition of ALI in which symptom duration is <2 weeks (Table 3).33,34 Category I refers to viable limbs that are not immediately threatened. Category II refers to threatened limbs. Category III limbs are marginally threatened and salvageable, if promptly treated. Category IIb are immediately threatened limbs that require immediate revascularization if salvage is to be accomplished. Category III are irreversibly damaged limbs, in which case resultant major tissue loss or permanent nerve damage is inevitable.34

10.1. Clinical Presentation of ALI: Recommendations

<table>
<thead>
<tr>
<th>COR</th>
<th>LOE</th>
<th>Recommendations</th>
</tr>
</thead>
<tbody>
<tr>
<td>I</td>
<td>C-E0</td>
<td>Patients with ALI should be emergently evaluated by a clinician with sufficient experience to assess limb viability and implement appropriate therapy.</td>
</tr>
<tr>
<td>N/A</td>
<td></td>
<td>Patients with ALI should be rapidly evaluated by a vascular specialist if one is available. Depending on local clinical expertise, the vascular specialist may be a vascular surgeon, interventional radiologist, cardiologist, or a general surgeon with specialized training and experience in treating PAD. If such expertise is not locally or rapidly available, there should be strong consideration of transfer of the patient to a facility with such resources. The more advanced the degree of ischemia, the more rapidly the communication (including communication about potential patient transfer) needs to occur.</td>
</tr>
<tr>
<td>I</td>
<td>C-LD</td>
<td>In patients with suspected ALI, initial clinical evaluation should rapidly assess limb viability and potential for salvage and does not require imaging.307-308</td>
</tr>
</tbody>
</table>

ALI is a medical emergency and must be recognized rapidly. The time constraint is due to the period that skeletal muscle will tolerate ischemia—roughly 4 to 6 hours.362 A rapid assessment of limb viability and ability to restore arterial blood flow should be performed by a clinician able to either complete the revascularization or triage the patient.358 Lower extremity symptoms in ALI can include both pain and loss of function. The longer these symptoms are present, the less likely the possibility of limb salvage.360,361 Clinical assessment must include symptom duration, pain intensity, and motor and sensory deficit severity to distinguish a threatened from a nonviable extremity (Figure 3). The bedside assessment should include arterial and venous examination with a handheld continuous-wave Doppler because of the inaccuracy of pulse palpation.34 The loss of dopplerable arterial signal indicates that the limb is threatened. The absence of both arterial and venous Doppler signal indicates that the limb may be irreversibly damaged (nonsalvageable). Comorbidities should be investigated and managed aggressively, but this must not delay therapy. Even in the setting of rapid and effective revascularization, the 1-year morbidity and mortality rates associated with ALI are high.362,363
Figure 3. Diagnosis and Management of ALI.\textsuperscript{33,34} Colors correspond to Class of Recommendation in Table 1. ALI indicates acute limb ischemia.

### 10.2. Medical Therapy for ALI: Recommendations

**Recommendation for ALI Medical Therapy**

<table>
<thead>
<tr>
<th>COR</th>
<th>LOE</th>
<th>Recommendation</th>
</tr>
</thead>
<tbody>
<tr>
<td>I</td>
<td>C-EO</td>
<td>In patients with ALI, systemic anticoagulation with heparin should be administered unless contraindicated.</td>
</tr>
</tbody>
</table>

N/A  
Heparin (generally intravenous unfractionated heparin) is given to all patients acutely.\textsuperscript{35,36} This can stop thrombus propagation and may provide an anti-inflammatory effect that lessens the ischemia. Patients who have received heparin before the onset of ALI and have a decrease in platelet count may have heparin-induced thrombocytopenia.\textsuperscript{365,366} In this situation, a direct thrombin inhibitor is given, rather than heparin, if heparin-induced thrombocytopenia with thrombosis is suspected.

### 10.3. Revascularization for ALI: Recommendations

**Recommendations for Revascularization for ALI**

<table>
<thead>
<tr>
<th>COR</th>
<th>LOE</th>
<th>Recommendations</th>
</tr>
</thead>
<tbody>
<tr>
<td>I</td>
<td>C-LD</td>
<td>In patients with ALI, the revascularization strategy should be determined by local resources and patient factors (eg, etiology and degree of ischemia).\textsuperscript{367-369}</td>
</tr>
</tbody>
</table>

For marginally or immediately threatened limbs (Category IIa and IIb ALI [Figure 3]), revascularization should be performed emergently (within 6 hours). For viable limbs (Category I ALI [Figure 3]), revascularization should be performed on an urgent basis (within 6–24 hours). The revascularization strategy can range from catheter-directed thrombolysis to surgical thromboembolectomy. Available facilities and clinical expertise are factors that should be considered when determining the revascularization strategy. The technique that will provide the most rapid restoration of arterial flow with the least risk to the patient should be selected. For example, catheter-directed thrombolysis can provide rapid restoration of arterial flow to a viable or marginally threatened limb, particularly in the setting of recent occlusion, thrombosis of synthetic grafts, and stent thrombosis.\textsuperscript{367} If this is not available locally, surgical options for timely revascularization should be considered, along with the feasibility of timely transfer to a facility with the necessary expertise.

See Online Data Supplement 47.
Recommendations for Revascularization for ALI (Continued)

<table>
<thead>
<tr>
<th>COR</th>
<th>LOE</th>
<th>Recommendations</th>
</tr>
</thead>
<tbody>
<tr>
<td>I</td>
<td>C-LD</td>
<td>Amputation should be performed as the first procedure in patients with a nonsalvageable limb.372,373</td>
</tr>
</tbody>
</table>

For patients with Category III ALI (Figure 3), amputation should be performed as the index procedure. Prolonged duration of ischemia is the most common factor in patients requiring amputation for treatment of ALI. The risks associated with reconstruction outweigh the potential benefit in a limb that is already insensitive or immobile because of prolonged ischemia. Patients who have an insensitive and immobile limb in the setting of prolonged ischemia (>6 to 8 hours) are unlikely to have potential for limb salvage.34,361 In addition, in this setting the reperfusion and circulation of ischemic metabolites can result in multigang failure and cardiovascular collapse. However, if pain can be controlled and there is no evidence of infection, amputation may be deferred if this meets with the patient’s goals.

I C-LD Patients with ALI should be monitored and treated (eg, fasciotomy) for compartment syndrome after revascularization.372,373 |

The lower extremity muscles reside in compartments, surrounded by fascia and bones. Reperfusion to ischemic muscles can cause cellular edema, resulting in increased compartment pressure. When compartment pressure is >30 mm Hg, there is capillary and venuel compression that leads to malperfusion of the muscle; this is compartment syndrome. Fasciotomy is indicated when the compartment pressure increases. Measurement of intracomartment pressure is not always easily accessible. In such cases, evaluation for fasciotomy is prompted by development of increased pain, tense muscle, or nerve injury. Fasciotomy should be considered for patients with Category IIb ischemia for whom the time to revascularization is >4 hours.

IIa B-NR In patients with ALI with a salvageable limb, percutaneous mechanical thrombectomy can be useful as adjunctive therapy to thrombolysis.374–378 |

Multiple nonrandomized studies have suggested that percutaneous mechanical thrombectomy in combination with pharmacological therapy can be beneficial in the treatment of threatened limbs.374–378

IIa C-LD In patients with ALI due to embolism and with a salvageable limb, surgical thromboembolectomy can be effective.379–381 |

Patients with arterial embolism and an absent pulse ipsilateral to the ischemic limb can be treated by exposure of an artery in the affected limb and balloon-catheter thromboembolectomy. These patients may benefit from adjunctive intraoperative fibrinolitics. In the event that thromboembolectomy does not restore arterial flow, bypass can be performed.382–383

IIb C-LD The usefulness of ultrasound-accelerated catheter-based thrombolysis for patients with ALI with a salvageable limb is unknown.384–386 |

The use of ultrasound-accelerated catheter delivery of thrombolytic agents has been published in case series384 and retrospective analyses.385 However, the single RCT comparing this technique to standard catheter-based thrombolytic therapy failed to demonstrate a difference in outcomes, including bleeding, despite a lower total amount of lytic delivered.386

10.4. Diagnostic Evaluation of the Cause of ALI: Recommendations

Recommendations for Diagnostic Evaluation of the Cause of ALI

<table>
<thead>
<tr>
<th>COR</th>
<th>LOE</th>
<th>Recommendations</th>
</tr>
</thead>
<tbody>
<tr>
<td>I</td>
<td>C-EO</td>
<td>In the patient with ALI, a comprehensive history should be obtained to determine the cause of thrombosis and/or embolization.</td>
</tr>
</tbody>
</table>

N/A

In addition to identifying a known history of PAD, the history should focus on uncovering clinical evidence of other conditions that can result in ALI through either embolic or thrombotic mechanisms. These conditions include atrial fibrillation, left ventricular thrombus, aortic dissection, trauma, hypercoagulable state, and presence of a limb artery bypass graft. The clinical history should identify the presence or absence of a history of MI, symptoms and signs of left ventricular dysfunction resulting in congestive heart failure, or possible endocarditis. The history should evaluate for possibility of deep vein thrombosis with intracardiac shunt (eg, patent foramen ovale or other that may result in paradoxical arterial embolism), hypercoagulable state, and family history of thrombosis.
### 11. LONGITUDINAL FOLLOW-UP: RECOMMENDATIONS

PAD is a lifelong chronic medical condition. Ongoing care focuses on cardiovascular risk reduction with medical therapy, optimizing functional status with structured exercise and, when indicated, revascularization.

#### Recommendations for Longitudinal Follow-Up

<table>
<thead>
<tr>
<th>COR</th>
<th>LOE</th>
<th>Recommendations</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ia</td>
<td>C-LD</td>
<td>Duplex ultrasound is reasonable for routine surveillance after endovascular procedures in patients with PAD.397–399 See Online Data Supplement 52. Studies have developed duplex ultrasound diagnostic criteria for diagnosing restenosis at the site of endovascular revascularization. Diagnostic criteria need to be customized to the location (eg, iliac or superficial femoral artery) and type of intervention (eg, angioplasty, uncovered stent, or covered stent). The optimal timing for surveillance after endovascular procedures is unclear.395–399 There are limited outcome data on routine duplex surveillance versus clinical surveillance plus the ABI after endovascular revascularization.397–399 The value of duplex ultrasound may be greater in cases with higher rates of restenosis, such as after interventions to treat very long lesions or occlusions.401</td>
</tr>
<tr>
<td>I</td>
<td>C-EO</td>
<td>Patients with PAD should be followed up with periodic clinical evaluation and ABI measurement. N/A In addition to the clinical evaluation of cardiovascular risk factors, functional status, and adherence to medical therapy and smoking cessation, patients with PAD who have previously undergone lower extremity revascularization (surgical and/or endovascular) require additional ongoing assessment and care. Follow-up visits after revascularization should include reassessment of the patient's limb symptoms and interval change in functional status, as well as participation in a structured exercise program. Pulse examination and ABI are included in the assessment. A change in ABI of 0.15 is considered clinically significant.240 See Online Data Supplements 51 and 52.</td>
</tr>
<tr>
<td>Ia</td>
<td>B-R</td>
<td>Duplex ultrasound can be beneficial for routine surveillance of infrainguinal, autogenous vein bypass grafts in patients with PAD.389–395 See Online Data Supplements 51 and 52. Duplex graft surveillance focuses on the identification of high-grade stenosis (eg, peak systolic velocity &gt;300 cm/s and peak systolic velocity ratio across the stenosis &gt;3.5) or impending graft failure (eg, PSV &lt;40 cm/s).292,395 Detection of a graft stenosis prompts the consideration of further revascularization to treat the stenosis and maintain graft patency. Duplex may detect significant stenoses that may not be detected by a decline in ABI.294 Although case series have demonstrated high rates of primary assisted patency with a duplex ultrasound-surveillance strategy, RCTs of duplex surveillance versus clinical surveillance with the ABI have demonstrated mixed results in terms of a benefit on patency and limb outcomes.389,393,396</td>
</tr>
<tr>
<td>Ia</td>
<td>C-EO</td>
<td>In the patient with a history of ALI, testing for a cardiovascular cause of thromboembolism can be useful. Treatment of ALI should not be delayed for testing for the underlying cause of the limb ischemia. Delay from symptom onset to revascularization is a major determinant of outcome.363,365 The evaluation of a cardiovascular cause of ALI is most useful in the patient without underlying PAD. Evaluation for cardiovascular cause includes electrocardiogram or additional heart rhythm monitoring to detect atrial fibrillation, electrocardiogram to detect evidence of MI, and echocardiography to further determine whether there is a cardiac etiology for thromboembolism, such as valvular vegetation, left atrial or left ventricular thrombus, or intracardiac shunt.367</td>
</tr>
<tr>
<td>N/A</td>
<td></td>
<td>See Online Data Supplements 51 and 52. A comprehensive care plan for patients with PAD includes periodic clinical evaluation by a healthcare provider with experience in the care of vascular patients. Clinical evaluation should include assessment of cardiovascular risk factors, assessment of adherence to medical therapy, and re-evaluation of smoking cessation efforts. Comprehensive lifestyle modification, including heart-healthy nutrition, is encouraged.27 Patients with PAD should also undergo periodic assessment of limb symptoms, functional status, and their ability to participate in vocational and recreational activities. Ongoing participation in a structured exercise program should be facilitated. Foot examination and patient counseling about healthy foot behaviors in PAD are addressed in Section 7.</td>

2016 AHA/ACC Lower Extremity PAD Guideline

Circulation. 2017;135:e726–e779. DOI: 10.1161/CIR.0000000000000471

March 21, 2017
12. EVIDENCE GAPS AND FUTURE RESEARCH DIRECTIONS

In performing the evidence review and in developing the present guidelines, the writing committee identified the following critical evidence gaps and future directions for PAD-related research:

- Basic science and translational studies to better understand the vascular biology of endovascular therapies and bypass grafting and to develop new methods for preventing restenosis after revascularization.
- Determination of risk factors for progression from asymptomatic PAD to symptomatic disease, including CLI.
- RCTs needed to determine the value of using the ABI to identify asymptomatic patients with PAD for therapies to reduce cardiovascular risk (eg, antiplatelet agents, statins, and other therapies).
- Advancement in PAD diagnostics, such as technologies for simplified yet highly accurate measurement of the ABI and tools for more reliable noninvasive perfusion assessment in CLI.
- Comparative-effectiveness studies to determine the optimal antiplatelet therapy (drug or drugs and dosage) for prevention of cardiovascular and limb-related events in patients with PAD.
- Development of additional medical therapies for claudication—an area of unmet medical need with a currently limited research pipeline.\(^{404}\)
- Studies to investigate the role of dietary intervention, in addition to statin therapy, to improve outcome and modify the natural history of PAD.
- Additional research to identify the best community- or home-based exercise programs for patients with PAD to maximize functional status and improve QoL, as well as the role of such exercise programs before or in addition to revascularization.
- Development and validation of improved clinical classification systems for PAD that incorporate symptoms, anatomic factors, and patient-specific risk factors and can be used to predict clinical outcome and optimize treatment approach. An example of a recently developed classification system is the Society for Vascular Surgery limb classification system, based on wound, ischemia, and foot infection (WIfI), which has been validated in different populations and may permit more meaningful prognosis in patients with CLI.\(^{405-409}\)
- Comparative- and cost-effectiveness studies of the different endovascular technologies for treatment of claudication and CLI, including drug-coated balloons and DES. Studies should include patient-centered endpoints, such as functional parameters, time to wound healing, and QoL, in addition to standard patency-focused outcomes. These studies could then be incorporated into value-based clinical algorithms for approach to revascularization for claudication and CLI.
- Additional studies to demonstrate the impact of multisocietal registries on clinical outcomes and appropriate use. At present, these include the Vascular Quality Initiative (VQI), the National Cardiovascular Data Registry Peripheral Vascular Intervention Registry\(^{\text{TM}}\) (PVI Registry\(^{\text{TM}}\)), and the National Radiology Data Registry for Interventional Radiology (NRDR). These registries provide an opportunity to obtain “real-world” data on surgical and endovascular procedures for PAD and to improve quality by providing feedback to participating centers. Future efforts should incorporate these registries into interventional RCTs and postmarketing studies of PAD-related devices.

13. ADVOCACY PRIORITIES

The writing committee identified 3 priorities for multisocietal advocacy initiatives to improve health care for patients with PAD. First, the writing committee supports the availability of the ABI as the initial diagnostic test to establish the diagnosis of PAD in patients with history or physical examination findings suggestive of PAD (Table 5). Although the ABI test is generally reimbursed by third-party payers for patients with classic claudication or lower extremity wounds, payers may not provide reimbursement for the ABI with other findings suggestive of PAD, such as lower extremity pulse abnormalities or femoral bruits. The writing committee affirms the importance of confirming the diagnosis of PAD in such patients to allow for GDMT as delineated in this document. Second, the writing committee supports the vital importance of insuring access to supervised exercise programs for patients with PAD. Although extensive high-quality evidence supports supervised exercise programs to improve functional status and QoL, only a minority of patients with PAD participate in such programs because of lack of reimbursement by third-party payers. Third, the writing committee recognizes the need for incorporation of patient-centered outcomes into the process of regulatory approval of new medical therapies and revascularization technologies. For revascularization technologies, regulatory approval is driven primarily by data on angiographic efficacy (ie, target lesion patency) and safety endpoints. The nature of the functional limitation associated with PAD warrants the incorporation of patient-centered outcomes, such as functional parameters and QoL, into the efficacy outcomes for the approval process.

This table represents the relationships of committee members with industry and other entities that were determined to be relevant to this document. These relationships were reviewed and updated in conjunction with all meetings and/or conference calls of the writing committee during the document development process. The table does not necessarily reflect relationships with industry at the time of publication. A person is deemed to have a significant interest in a business if the interest represents ownership of ≥5% of the voting stock or share of the business entity, or ownership of ≥$5000 of the fair market value of the business entity; or if funds received by the person from the business entity exceed 5% of the person’s gross income for the previous year. Relationships that exist with no financial benefit are also included for the purpose of transparency. Relationships in this table are modest unless otherwise noted. According to the ACC/AHA, a person has a relevant relationship IF: a) the relationship or interest relates to the same or similar subject matter, intellectual property or asset, topic, or issue addressed in the document; or b) the company/entity (with whom the relationship exists) makes a drug, drug class, or device addressed in the document, or makes a competing drug or device addressed in the document; or c) the person or a member of the person’s household, has a reasonable potential for financial, professional, or other personal gain or loss as a result of the issues/content addressed in the document.

*Writing committee members are required to recuse themselves from voting on sections to which their specific relationships with industry and other entities may apply.

†Significant relationship.

‡No financial benefit.

ACC indicates American College of Cardiology; AHA, American Heart Association; DSMB, data safety monitoring board; and VA, Veterans Affairs.

This table represents all relationships of reviewers with industry and other entities that were reported by authors, including those not deemed to be relevant to this document, at the time this document was under development. The table does not necessarily reflect relationships with industry at the time of publication. A person is deemed to have a significant interest in a business if the interest represents ownership of ≥5% of the voting stock or share of the business entity, or ownership of ≥$5000 of the fair market value of the business entity; or if funds received by the person from the business entity exceed 5% of the person’s gross income for the previous year. Relationships that exist with no financial benefit are also included for the purpose of transparency. Relationships in this table are modest unless otherwise noted. Please refer to http://www.acc.org/guidelines/about-guidelines-and-clinical-documents/relationships-with-industry-policy for definitions of disclosure categories or additional information about the ACC/AHA Disclosure Policy for Writing Committees.

*Significant relationship.
†No financial benefit.

Correction to: 2016 AHA/ACC Guideline on the Management of Patients With Lower Extremity Peripheral Artery Disease: A Report of the American College of Cardiology/American Heart Association Task Force on Clinical Practice Guidelines

In the article by Gerhard-Herman et al, "2016 AHA/ACC Guideline on the Management of Patients With Lower Extremity Peripheral Artery Disease: A Report of the American College of Cardiology/American Heart Association Task Force on Clinical Practice Guidelines," which published online November 13, 2016, and appeared in the March 21, 2017, issue of the journal (Circulation. 2017;135:e726–e779. DOI: 10.1161/CIR.0000000000000471), several corrections were needed.

1. On page e728, left column, in the third paragraph, the following sentence has been deleted: “Recommendations developed by the writing committee on the basis of the systematic review are marked as “SR.” The deletion reflects the fact that a systematic review was not produced for this document.

2. On page e733, in section "2. Clinical Assessment for PAD," the first sentence read, “Evaluating the patient for PAD begins with the clinical history, review of systems, and physical examination.” It has been updated to read, “Evaluating the patient for PAD begins with the clinical history, review of symptoms, and physical examination.”

3. On page e741, in section “5.1. Antiplatelet Agents: Recommendations,” the recommendations table, in the Class IA recommendation supporting text, the third sentence read, “Among patients patients with....” It has been updated to read, “Among patients with....”

4. On page e743, in section “5.3. Antihypertensive Agents: Recommendations,” the recommendations table, in the Class IIa recommendation supporting text, the fifth sentence read, “ONTARGET (Ongoing Telmisartan Alone and in Combination With Ramipril Global Endpoint Trial) compared telmisartan, ramipril, and combination therapy in patients with cardiovascular disease, including PAD, and/or diabetes mellitus.” It has been updated to read, “ONTARGET (Ongoing Telmisartan Alone and in Combination With Ramipril Global Endpoint Trial) compared telmisartan, ramipril, and combination therapy in patients with cardiovascular disease, including PAD, and/or diabetes mellitus.”

5. On page e751, in section “9.1. Revascularization for CLI: Recommendations,” the recommendations table, in the Class IB-NR recommendation supporting text, the penultimate sentence read, “Multiple RCTs comparing contemporary surgical and endovascular treatment for patients with CLI are ongoing.” It has been updated to read, “Multiple RCTs comparing contemporary surgical and endovascular treatment for patients with CLI are ongoing.”

6. On page e751, in section “9.1.1. Endovascular Revascularization for CLI: Recommendations,” the recommendations table, in the Class IB-R recommendation supporting text, the penultimate sentence read, “Multiple RCTs comparing contemporary surgical and endovascular treatment for patients with CLI are ongoing.” It has been updated to read, “Multiple RCTs comparing contemporary surgical and endovascular treatment for patients with CLI are ongoing.”
7. On page e753, in section “9.2. Wound Healing Therapies for CLI: Recommendations,” the recommendations table, in the Class IC-LD recommendation, supporting text, the second sentence read, “To date, there are no trials or high-quality studies that have focused on wound healing adjuncts in limbs with severe PAD (e.g., topical cytokine ointments, skin substitutes, cell-based therapies intended to optimize wound healing).” It has been updated to read, “To date, there are no RCTs or high-quality studies that have focused on wound healing adjuncts in limbs with severe PAD (e.g., topical cytokine ointments, skin substitutes, cell-based therapies intended to optimize wound healing).”

8. On page e754, in section “10.1. Clinical Presentation of ALI: Recommendations,” the recommendations table, in the Class IC-LD recommendation supporting text, the penultimate sentence read, “Comorbidities should be investigated…but must this not delay therapy.” is updated to read, “Comorbidities should be investigated…but this must not delay therapy.”

These corrections have been made to the current online version of the article, which is available at http://circ.ahajournals.org/content/135/12/e726.

</table>

This table represents all relationships of committee members with industry and other entities that were reported by authors, including those not deemed to be relevant to this document, at the time this document was under development. The table does not necessarily reflect relationships with industry at the time of publication. A person is deemed to have a significant interest in a business if the interest represents ownership of ≥5% of the voting stock or share of the business entity, or ownership of ≥$5,000 of the fair market value of the business entity; or if funds received by the person from the business entity exceed 5% of the person’s gross income for the previous year. Relationships that exist with no financial benefit are also included for the purpose of transparency. Relationships in this table are modest unless otherwise noted. Please refer to [http://www.acc.org/guidelines/about-guidelines-and-clinical-documents/guidelines-and-documents-task-forces](http://www.acc.org/guidelines/about-guidelines-and-clinical-documents/guidelines-and-documents-task-forces) for definitions of disclosure categories or additional information about the ACC/AHA Disclosure Policy for Writing Committees.

*Significant relationship.
†No financial benefit.

DSMB indicates data safety monitoring board; IAC, Intersocietal Accreditation Commission; NHLBI, National Heart, Lung, and Blood Institute; NIH, National Institute of Health; and PCORI, Patient-Centered Outcomes Research Institute.

Methodology and Evidence Review

The recommendations listed in this guideline are, whenever possible, evidence based. An initial extensive evidence review, which included literature derived from research involving human subjects, published in English, and indexed in MEDLINE (through PubMed), EMBASE, the Cochrane Library, the Agency for Healthcare Research and Quality, and other selected databases relevant to this guideline, was conducted from January through September 2015. Key search words included but were not limited to the following: acute limb ischemia, angioplasty, ankle-brachial index, anticoagulation, antiplatelet therapy, atypical leg symptoms, blood pressure lowering/hypertension, bypass graft/bypass grafting/surgical bypass, cilostazol, claudication/intermittent claudication, critical limb ischemia/severe limb ischemia, diabetes, diagnostic testing, endovascular therapy, exercise rehabilitation/exercise therapy/exercise training/supervised exercise, lower extremity/foot wound/ulcer, peripheral artery disease/peripheral arterial disease/peripheral vascular disease/lower extremity arterial disease, smoking/smoking cessation, statin, stenting, and vascular surgery. Additional relevant studies published through September 2016, during the guideline writing process, were also considered by the writing committee, and added to the evidence tables when appropriate.

<td>Rose GA 1962(1) 13974778</td>
<td>Study type: Cross-sectional study pts with and without claudication given claudication questionnaire; validated to clinical Dx of IC. Study also validated a questionnaire for angina pectoris. Size: n=37 pts with &quot;undoubted&quot; IC; n=18 controls; total n=55 pts</td>
<td>Inclusion criteria: • &quot;Most&quot; IC/PAD pts had angiograms; non-PAD pts had other causes of leg pain; • IC group mean age 57.1 y; other leg pain group mean age 48.2 y. Exclusion criteria: N/A</td>
<td>Results: • 34/37 claudicants met criteria for IC by questionnaire (92% sensitive) • Of 18 other leg pain controls none met criteria for IC by questionnaire (100% specific)</td>
<td>• Put forth a concept of classic IC • Very small sample size for validation of questionnaire. Highly restrictive definition of IC (will exclude pts with atypical leg symptoms). • High specificity for IC/PAD. • Later studies reported much lower sensitivity of this questionnaire (68%), specificity (100%) Richard JL, Ducimetiere P, Elgrishi I, et al. Rev Epidemiol Med Sci Sante Publ 1972 (French)</td>
</tr>
<tr>
<td>Leng GC, Fowkes FG 1992(2) 1474406</td>
<td>Study type: Cross-sectional study of questionnaire vs. MD clinical assessment/ABI±exercise. Study developed modification of Rose/WHO Questionnaire (phase I/development) and validated the subsequent Edinburgh Claudication Questionnaire (phase II/validation). Size: Phase I (development) n=647; 586 with claudication/PAD and 61 with other leg pain. Phase II (validation)</td>
<td>Inclusion criteria: • Pts with leg symptoms seen in Vascular Clinic who had undergone ABI (Phase I/development). • Vascular clinic pts with leg pain and community pts seeing a GP (Phase II/validation). Exclusion criteria: N/A</td>
<td>Results: • Performance of WHO/Rose in the dataset—Sensitivity 60%; specificity of 91% • Does the pain every disappear while still walking, poorest performing element of WHO/Rose • Edinburgh Claudication Questionnaire performance vs. ABI/clinical assessment by clinician: • Sensitivity: 91.3% community, 82.8% vascular clinic • Specificity: 99.3% community, 100%</td>
<td>• Identified key issues with WHO/Rose Questionnaire to develop Edinburgh Claudication Questionnaire. Maintained 5 questions from WHO/Rose (or with minor modification), removed 2 questions, diagram included for pts to localize site of pain (front and back of both legs)</td>
</tr>
</tbody>
</table>
Criqui MH, et al. 1996(3) 9546918

**Study type:** Cross-sectional study of modified WHO/ROSE questionnaire (San Diego Claudication Questionnaire) vs. ABI/TBI/posterior tibial flow velocity

**Size:** n=508 pts (980 limbs for analysis)

**Inclusion criteria:**
- Pts seen during preceding 10 y at San Diego VA Hospital or UCSD Medical Center vascular labs invited to participate
- Mean age 68 y
- Vascular lab studies used to characterize pts as:
  - Optimal (no disease)
  - Borderline Normal
  - Isolated small vessel
  - Isolated posterior tibial
  - Moderate PAD (ABI 0.61–0.9)
  - Severe PAD (ABI <0.6)

**Exclusion criteria:** N/A

**Results:** Questionnaire identified wide spectrum of clinical sx in pts with documented PAD, including no sx, pain at rest, noncalf pain, non-Rose calf claudication, Rose calf claudication

- PPV: 91% community, 100% vascular clinic
- NPV: 99% community, 81% vascular clinic

McDermott MM, et al. 1999(4) 10030313

**Study type:** Cross-sectional study of pts with and without PAD administered San Diego Claudication questionnaire, ABI assessment

**Size:** n=268 pts (137 known PAD from vascular lab; 26 known PAD from general medical practice; 105 pts without PAD)

**Inclusion criteria:**
- Pts with and without PAD identified from (vascular. lab, general medical clinics)
- PAD defined as ABI <0.9

**Exclusion criteria:** Low MMSE, nursing home residents, wheelchair bound, pts with major lower extremity amputation, non-English speakers, life expectancy <6 mo, noncompressible ABI >1.50

**Results:** Grouped pts according to 4 categories based on San Diego Claudication Questionnaire:
1. No exertional leg symptoms
2. IC (classic)
3. Atypical exertional leg symptoms
4. Pain at rest
- Among N=137 PAD pts identified from vascular lab:
  - 15.3% had no exertional leg symptoms
  - 28.5% had IC (classic)
  - 25.5% atypical exertional leg symptoms
  - 30.7% pain at rest.
- Among PAD pts (n=163), factors significantly associated absence of exertional leg sx: older age, male sex, DM, PAD pt recruited from general medicine clinic rather than vascular lab.
- Among PAD pts (N=163), factors
| McDermott MM, et al. 2001(5) 11585483 | **Study type:** Cross-sectional study of pts with and without PAD identified from 3 medical centers in same city. Pts underwent functional capacity assessments (6min walk, 4 M walk, chair raises), assessment of physical activity, ABI, questionnaires  
**Size:** n=590 pts (460 with PAD; 130 without PAD) | **Inclusion criteria:**  
- Pts with and without PAD identified from 3 medical centers (vascular lab, general medical practice)  
- PAD confirmed with study ABI (average leg pressure method) and required ABI <0.9  
**Exclusion criteria:**  
- “PAD” pts with normal ABI at study visit  
- Dementia  
- Nursing home residents  
- Wheelchair bound  
- Pts with major lower extremity amputation  
- Recent major surgery  
- Non-English speakers | **Results:**  
- Grouped pts according to 6 types of leg symptoms in 4 overall categories:  
  1. IC (classic)  
  2. Atypical exertional leg pain (carry on/stop)  
  3. No exertional leg pain (active/inactive walk >6 blocks/wk Yes/No)  
  4. Leg pain on exertion at rest  
- Among confirmed PAD pts:  
  32% had IC; 19% leg pain on exertion and at rest; 29% atypical exertional leg pain (9% carry on; 20% stop); 20% no exertional leg pain.  
- PAD pts in the non-IC groups also demonstrated functional impairment in terms of 6 min walk, 4 meter walk.  
- No exertional leg pain/inactive and exertional and rest pain groups with worse functional capacity than IC group.  
- Atypical exertional leg pain/carry on group with better outcomes on 6 min walk than IC group. | **More data on wide spectrum of leg sx among pts with PAD and demonstration that functional impairment is common regardless of type of leg symptoms.** |

| Hirsch AT, et al. 2001(6) 11560536 | **Study type:** Multi-center cross-sectional study conducted at 350 primary care practices in the US. Pts enrolled underwent San Diego Claudication Questionnaire, medical and CV Hx/risk factor assessment, BP, anthropomorphics, and ABI assessment. Pts. identified as having PAD (and their providers) further asked about awareness of the PAD Dx. | **Inclusion criterion:**  
- Age ≥70 y; Age 50–69 y with DM or at least 10 pack-year tobacco Hx  
- PAD (lower leg pressure method) defined as ABI ≤0.9 in either leg  
**Exclusion criteria:** N/A | **Results:**  
- Prevalence of PAD in this cohort was 29%  
- Among 1865 pts with PAD (mean ABI 0.78): 5.5%–15.3% Rose claudication; 46.3%–61.7% atypical leg sx; 23.3%–48.3% no pain; **rates reported for new Dx/prior Dx and for PAD only and PAD+CVD  
- More data on wide spectrum of leg sx among pts with PAD; only approximately 5%–15% of ABI confirmed PAD pts have classic Rose claudication. Majority have atypical non-Rose leg sx or no leg pain. |

| Wassel et al. 2011(9) 21920269        | n=2,404                | Observational population-based study of current or former employees of the University of California, San Diego, and their significant others, as well as 193 other volunteers and their significant others. | Men and women age 19–91 y who completed the baseline visit in the San Diego Population Study | **1^ endpoint**: Prevalence of PAD in the study population                                        | N/A                                                              |
| Clark CE et al., 2012(10) 22293369 | **Study type:** Meta-analysis  
**Size:** n=20 studies | **Inclusion criteria:**  
- Cohort or cross-sectional studies of differences in BP between arms  
- Age ≥18 y  
- Data for central vascular disease, PVD, or death  
**Exclusion criteria:**  
- Case reports | **1° endpoint:** PVD  
**Results:**  
- Significant association of a difference of ≥10 mmHg and SS (risk ratio: 8.8; 95% CI: 3.6–21.2)  
- Significant association in noninvasive studies of a difference of ≥15 mmHg and PVD (risk ratio: 2.5, 95% CI: 1.6–3.8) (sensitivity: 15%; 95% CI: 9–23) (specificity: 96%; 95% CI: 94–98)  
- Significant association in noninvasive studies of a difference of ≥15 mmHg and pre-existing cerebrovascular disease (risk ratio: 1.6, 95% CI: 1.1–2.48) (sensitivity: 8%; 95% CI: 2–26) (specificity: 93%; 95% CI: 86–97)  
- Significant association in noninvasive studies of a difference of ≥15 mmHg and cardiovascular mortality (HR: 1.7, 95% CI: 1.1–2.5)  
- Significant association in noninvasive studies of a difference of ≥15 mmHg and all-cause mortality (HR: 1.6; 95% CI: 1.1–2.3)  
- Significant association of ≥10 mmHg and PVD (RR: 2.4; 95% CI: 1.5–3.9) (sensitivity: 32%; 95%CI: 23–41) (specificity: 91%, 95% CI: 86–94)  
- **A difference in SBP of ≥10 mm Hg or of ≥15 mm Hg, between arms might help to identify pts who need further vascular assessment.**  
- **A difference of ≥15 mm Hg could be a useful indicator of risk of vascular disease and death.** |  |
| --- | --- | --- | --- |
| Singh S et al., 2015(11) 26160261 | **Study type:** Meta-analysis of cohort studies  
**Size:** n=18 cohorts | **Inclusion criteria:**  
- Studies measuring BP simultaneously in arms or legs  
- Studies reporting CAD, cerebrovascular disease, PAD, subclavian stenosis, survival or mortality, and other relevant CV indices or outcomes.  
**Exclusion criteria:**  
- Studies that did not report a dichotomous outcome defined by a **1° endpoint:** Prevalence of PAD, CAD, cerebrovascular disease, subclavian stenosis, all-cause, and CV mortality  
**Results:**  
- Significant association between IASBPD of ≥10 mmHg and PAD (RR: 2.22; 95% CI: 1.41–3.5; p=0.0006) (sensitivity: 16.6%; 95% CI: 6.7–35.4) (specificity: 91.9%; 95% CI: 83.1–96.3)  
- Significant association of PAD at cutoff of 15 mmHg (RR: 1.91; 95% CI: 1.28–2.84)  
- **Inter-arm and leg BP differences are predictors of PAD. The IASBPD may be associated subclavian stenosis, high left ventricular mass effect, and higher brachial–ankle PWVs.** |  |
| Shadman R et al., 2004(12) 15358030 | **Study type:** Review of cohort studies  **Size:** n=4 cohorts with 4,223 pts (2,975 from 2 free-living cohorts and 1,248 from 2 clinical cohorts)  **Inclusion criteria:**  - Cohort A:  - Geographic defined population study  - Part of the Lipid Research Clinics protocol study  - Cohort B:  - Randomly selected from a database of UCSD employees and spouses  - Cohort C:  - Pt population in Chicago  - Cohort D:  - Pts who visited the San Diego Veterans Administration Medical Center or UCSD Medical Center vascular laboratories between 1990–1994 | **specific BP difference cutoff**  - (sensitivity: 25.1%; 95% CI 7.9–56.7)  - (specificity: 88.2%; 95% CI: 71.7–95.7).  - Significant association between inter-leg BP difference of ≥15 mmHg and PAD (RR: 11.87; 95% CI: 7.64–18.44).  - IASBPD of ≥10 mmHg was not associated with carotid-femoral PWV (standardized mean difference: 0.26; 95% CI: 0.15–0.68; p=0.21). One study demonstrated positive association between IASBPD of ≥10 mmHg and brachial ankle PWV (adjusted OR from multivariate model: 1.001; 95% CI: 1.000–1.001; p=0.022).  - Significant association of inter-leg BP difference of ≥15 mm Hg or more and brachial–ankle PWV (standardized mean difference: 0.68; 95% CI: 0.37–0.99; p=0.0001). | **1st endpoint:** Prevelance of SS  **Results:**  - SS was significantly (p<0.05) associated with past smoking (OR: 1.80), current smoking (OR: 2.61), and higher levels of SBP (OR: 1.90 per 20 mm Hg)  - Significant association between higher levels of HDL and SS (OR: 0.87 per 10 mg/dl)  - Significant association of SS and PAD (OR: 5.11, p<0.001)  - SS is correlated with current and past smoking histories, SBP, HDL levels (inversely), and the presence of PAD  - bilateral brachial BP measurements should routinely be performed in pts with an elevated risk profile, both to screen for SS, and to avoid missing a hypertension or PAD diagnosis because of unilateral pressure measurement in an obstructed arm |
**Exclusion criteria:**
- Cohort A: Missing data
- Cohort B: N/A
- Cohort C:
  - Wheelchair bound
  - Hx Foot or leg amputations
  - Nursing home residents
  - Non-English speaking
  - Hx dementia
- Cohort D: N/A

ABi indicates ankle-brachial index; BP, blood pressure; CI, confidence interval; CV, cardiovascular; DBP, diastolic blood pressure; GP, general practitioner; HR, hazard ratio; IASBPD, inter-arm systolic blood pressure; IC, intermittent claudication; LR, likelihood ratio; MMSE, Mini-Mental State Examination; N/A, not applicable; NPV, negative predictive value; OR, odds ratio; PAD, peripheral artery disease; PPV, positive predictive value; pt, patient; PVD, peripheral vascular disease; PWV, pulse wave velocity; RR, relative risk; SBP, systolic blood pressure; SS, subclavian artery stenosis; TBI, toe-brachial index; UCSD, University of California, San Diego; VA, veterans affairs; and WHO, World Health Organization.

**Evidence Table 2. Nonrandomized Trials, Observational Studies, and/or Registries of Physical Examination for Clinical Assessment for PAD—Section 2.1.**

- PAD Dx confirmed by reference standard: ABI, duplex, or angiogram  
- Data could be extracted into a 2 x 2 table  
- 17 studies met inclusion criteria | **Results:**  
**Physical Examination**  
**Skin changes**  
Skin cool to touch in affected leg:  
- LR PAD: 5.90; 95% CI 4.10–8.60  
Leg wound/sore:  
- LR PAD: 5.90; 95% CI: 2.60–13.40  
Discolored skin:  
- LR PAD: 2.80; 95% CI: 2.40–3.30  
Absence of cool skin, wound/sore did not lower likelihood of PAD  
**Bruit**  
Presence of ≥1 bruit | • In general, presence of physical findings increases likelihood of PAD  
• Entirely normal pulse exam and absence of any bruits decrease likelihood of PAD  
• Sensitivities/specificities not reported in this review |
**Exclusion criteria:** N/A

**Pulse Palpation**

- Any* pulse abnormality
  - LR PAD: 4.70; 95% CI: 2.20–9.90
  - Absent/reduced

*any=femoral/popliteal/DP/PT

- Absence of any pulse abnormality:
  - LR PAD: 0.38; 95% CI: 0.23–0.64

Abnormal dorsalis pedis pulse less diagnostically useful than abnormal femoral or PT pulse

- DP not palpable in 8.1% of healthy pts
- PT not palpable in 2.9% of healthy pts

**Capillary Refill**

- Abnormal capillary refill time
  - LR PAD: 1.90; 95% CI: 1.20–3.20
  - Prolonged venous refill
  - LR mod/sev PAD: 3.60; 95% CI: 1.90–6.80

Normal venous refill time not informative to r/o PAD

---

**Study type:**
- Part of the EVADEC, prospective cohort study (cross-sectional analysis).
- Pts with no known vascular disease underwent physical examination followed by vascular studies (carotid, femoral ultrasound, ABI)

**Inclusion criteria:**
- 18–90 y (mean age 52 y)
- No known CVD
- Asx

**Exclusion criteria:** CV disease identified by medical record review

**Results**

- 14.5% of pts had any bruit or absent PT/DP pulse
  - *Femoral bruit*
    - +LR ipsilateral ABI <0.9: 2.90; 95% CI: 1.63–5.16
    - -LR ipsilateral ABI <0.9: 0.93; 95% CI: 0.88–0.98
  - *Absent PT pulse*
    - +LR ipsilateral ABI <0.9: 1.80; 95% CI: 1.08–3.01
    - -LR ipsilateral ABI <0.9: 0.94; 95% CI: 0.88–1.01
  - *Absent DP pulse*
    - +LR ipsilateral ABI <0.9: 2.01; 95% CI: 1.17–3.45
    - -LR ipsilateral ABI <0.9: 0.94; 95% CI: 0.88–1.00
  - *Absent DP+PT*
    - +LR ipsilateral ABI <0.9: 3.57; 95% CI: 1.93–6.60
    - -LR ipsilateral ABI <0.9: 0.93; 95% CI: 0.97–1.00

Interaction term for DM not significant

Interobserver agreement 97% for femoral bruit; 92% PT palpation; 92% DP palpation

---

Both presence of femoral bruit and absent pulses increase likelihood of PAD in asx pts without known PAD/CVD
bell of stethoscope

**Size**: n=2,736 eligible pts

**Interobserver variability substudy size**: 500 pts

Also reported on carotid bruit for Dx of carotid stenosis/plaque/increased IMT (did not affect LR)

---

**Study type**: Retrospective database analysis of pts who underwent ABI and had a physical examination documented in the CARDIOfile database between 12.2005–2.2010 at a single clinic

**Size**: n=1,236 eligible pts with complete data

**Inclusion criteria**: Pts who had ABI performed for suspected PAD or risk factors for PAD (Age >70 y, DM or smokers ages 50–69 y, intermediate Framingham Risk score)

**Exclusion criteria**: Pts with ABI >1.30 in either leg; incomplete physical examination in the database

**Definitions**
- PAD defined as ABI ≤0.9
- Pulses rated 0-3 scale; analysis absent vs. present
- Femoral bruits present/absent
- Claudication=leg sx with exercise gone within 5 min of rest.

**Results**: 28.1% of pts had an abnormal ABI in at least 1 leg (PAD)

- **Femoral bruit**
  - Sens 36.1%, Spec 92.0%
  - PPV 51.1%, NPV 86.2%, Accuracy 81.6%
  - +LR PAD 4.5
  - -LR PAD 0.69

- **PT pulse abnl**
  - Sens 70.0%, Spec 83.4%
  - PPV 49.3%, NPV 92.3%, Accuracy 80.9%
  - +LR PAD 4.2
  - -LR PAD 0.36

- **DP pulse abnl**
  - Sens 63.9%, Spec 80.6%
  - PPV 43.2%, NPV 90.7%, Accuracy 77.5%
  - +LR PAD 3.3
  - -LR PAD 0.45

**Absent DP and PT pulses+femoral bruit either side (vs. normal pulses, no femoral bruits)**
- Sens 58.2%, Spec 98.3%
- PPV 81%, NPV 94.9%, Accuracy 93.8%
- +LR PAD 34.2
- -LR PAD 0.43

- Completely normal exam (all ankle pulses present and no femoral bruits) has high accuracy for normal ABI/no PAD.
- Pulse abnormalities+femoral bruits makes Dx of PAD likely.
- Single abnormal physical findings increased likelihood of abnormal ABI (specific findings)
- Sensitivity of single abnormal physical examination findings lower; not as “reassuring” to rule out PAD/abnormal ABI

ABI indicates ankle-brachial index; CI indicates confidence interval; CVD, cardiovascular disease; CV, cardiovascular; DP, dorsalis pedis; Hx, history; IMT, intima-media thickness; LR, likelihood ratio; PPV, positive predictive value; PAD, peripheral artery disease; PT, posterior tibial; pt, patient; OR, odds ratio; RR, relative risk; sens, sensitivity; and spec, specificity.

| **Fowkes FG et al. 2010**<sup>(15) 20197530</sup> | **Aim:** To determine the effectiveness of ASA in preventing events in people with a low ABI identified on screening the general population.  
**Study type:** RCT  
**Size:** n=3,350 pts | **Inclusion criteria:** Men and women age 50–75 y  
**Exclusion criteria:**  
- Previous Hx of vascular disease, MI, or stroke;  
- Currently taking ASA or warfarin. | **Intervention:** 100 mg enteric coated ASA  
**Comparator:** Placebo | **1° endpoint:** Composite of initial fatal or nonfatal coronary event, stroke or revascularization. (ASA: 13.7; 95% CI: 11.8–15.9 vs. placebo: 13.3; 95% CI: 11.4–15.4, events per 1,000 person-y; HR: 1.03; 95% CI: 0.84–1.27)  
**1° Safety endpoint:** Major Hemorrhage: ASA: 2.5; 95% CI: 1.7–3.5 vs. placebo: 1.5; 95% CI: 0.9–2.3 per 1,000 person-y; HR: 1.71; 95% CI: 0.99–2.97 | • Initial vascular events defined as a composite of a 1° endpoint event or angina, IC, or TIA.  
ASA: 22.8; 95% CI: 20.2–25.6 vs. placebo: 22.9; 95% CI: 20.3–25.7 events per 1,000 person-y; HR: 1.00; 95% CI: 0.85–1.17  
• All-cause mortality ASA group, 176 deaths (12.8; 95% CI: 11.0–14.8 per 1,000 person-y); placebo group, 186 deaths (13.5; 95% CI: 11.6–15.6 per 1,000 person-y; HR: 0.95; 95% CI: 0.77–1.16)  
• Limitations: higher proportion of women, inclusion of pts with DM could have influenced results |
| **POPADAD Belch J et al. 2008**<sup>(16) 18927173</sup> | **Aim:** To determine whether ASA and antioxidant therapy, combined or alone, are more effective than placebo in reducing CVD events in pts with DM and Asx PAD.  
**Study type:** Multicenter, randomized, double blind, 2×2 factorial, placebo controlled trial.  
**Size:** n=1,276 pts | **Inclusion criteria:** Age ≥40 y with type 1 or type 2 DM and ABI of ≤0.99 but no Sx CVD.  
**Exclusion criteria:** People with: evidence of Sx vascular CVD; ASA or antioxidant therapy use on a regular basis; peptic ulceration, severe dyspepsia, a bleeding disorder, or intolerance to ASA; suspected serious physical illness (e.g., cancer), which could curtail life expectancy; psychiatric illness (reported by GP); pts with congenital heart disease; and pts unable to give informed consent | **Intervention and comparator:** Daily, 100 mg ASA tablet + antioxidant capsule (n=320); ASA + placebo capsule (n=318); placebo tablet + antioxidant capsule (n=320); or placebo tablet + placebo capsule (n=318). | **1° endpoint:**  
- Death from CHD or stroke, nonfatal MI or stroke, or amputation above the ankle for CLI; and death from CHD or stroke  
- 116 of 638 1° events in the ASA groups compared with 117 of 638 in the no ASA groups (18.2% vs. 18.3%; HR: 0.98; 95% CI: 0.76–1.26. 43 deaths from CHD or stroke occurred in the ASA groups compared with 35 in the no ASA groups (6.7% vs. 5.5%; HR: 1.23; 95% CI: 0.79–1.93).  
- No difference in treatment for ABI <0.90 | • Malignancy 0.76 (0.52–1.11),  
• GI bleeding, 0.90 (0.53–1.52)  
• Dyspepsia 0.77 (0.55–1.08),  
• Allergy 1.14 (0.80–1.63) |
**Study**

McDermott, MM et al. 2013(17) 23821089

**Study type:** RCT testing efficacy of a home-based walking exercise intervention vs. control in pts with PAD with and without claudication

**Size:** n=194 pts; 72.2% without claudication

**Inclusion criteria:**
- Age ≥65 y
- ABI ≤0.9 or 20% post exercise drop in ABI

**Exclusion criteria:**
- Lower extremity amputation
- Inability to walk ≥50 ft without stopping
- Inability to attend weekly sessions
- Walking impairment not from PAD

**Intervention:** Home-based group-mediated cognitive behavioral walking group

**Comparator:** Health education

**1° endpoint:** Change in 6-MWT between baseline and 6 mo

**Secondary outcomes:** Change in treadmill MWT; PFWT; physical activity; WIQ scores; PCS and MCS of SF-36

**Results:**
- 6-MWT:
  - Control: 347 m BL vs. 329 m 6 mo
  - Intervention: 372 m BL vs. 386 m 6 mo
- Modest improvement in 6-MWT distance after 6 mo of home-based exercise in pts with Asx PAD

1° indicates primary; ABI, ankle-brachial index; ASA, aspirin; Asx, asymptomatic; CI, confidence interval; BL, baseline; CVD, cardiovascular disease; CHD, coronary heart disease; GI, gastrointestinal; HR, hazard ratio, Hx, history; IC, intermittent claudication; MCS, mental component summary score; MWT, mean walking time; PAD, peripheral artery disease; PCS, physical component summary score; PFWT, pain-free walking time; pt, patient; Sx, symptomatic; RCT, randomized controlled trial; and TIA, transient ischemic attack

| Criqui MH, et al. 2005(18) 16246968  | Study type: Cross-sectional study 2,343 pts | Inclusion criteria:  
- Age 29–91 y  
- 1 of the following ethnicities: Non-Hispanic Whites, blacks, Hispanics, Asian | 1° endpoint: PAD prevalence  
Results:  
- 104 PAD cases (4.4%)  
- Blacks had a higher PAD prevalence than Non-Hispanic Whites (OR: 2.30; p>0.024)  
- Hispanics and Asians has a lower but nonsignificant lower PAD prevalence than Whites |  
- Suggests black ethnicity is a risk factor for PAD  
- No evidence of blacks being of higher susceptibility to CV risk factors to explain increased risk for PAD  
- Low prevalence of PAD (4.4%) |

| Selvin E, et al. 2004(19) 15262830 | Study type: Cross-sectional survey n=2,174 pts | Inclusion criteria:  
- Age ≥40 y  
- Participants of 1999–2000 NHANES  
- Participants with valid mean ABI blood pressure index | 1° endpoint: Frequency of detection, pt and physician awareness of diagnosis, and treatment intensity  
Results:  
- Prevalence of PAD in adults ≥40 y in U.S. was 4.3% (95% CI: 3.1%–5.5%)  
- Prevalence of PAD in adults ≥70 y in U.S. was 14.5% (95% CI: 10.8%–18.2%) |  
- PAD defined as ABI <0.90 in either leg  
- In the U.S., PAD affects >5 million adults.  
- PAD prevalence increases with age and disproportionately affects blacks.  
- Majority of pt with PAD have ≥1 |

**Study Type:** Meta-Analysis  
**Size:** n=16 population cohort studies, n=57,294 pts  
**Inclusion Criteria:** Availability of demographic and medical characteristics, baseline ABI measurement, follow-up data with information on fatal and nonfatal events  
**Exclusion Criteria:** Previous Hx of CHD  
**1st Endpoint:** Change in FRS CV risk prediction with addition of ABI  
**Results:**  
- Follow-up ranged from 3–6.7 y; 9924 (25% CVD) deaths during 480,325 person-years of follow-up.  
- CV mortality HR for different ABI levels: Reference=1.11–1.20; ABI ≤0.60=5.58 for men; 7.04 for women. 19% of men and 36% of women would change risk category with ABI added to FRS.  
- ABI provided independent risk information and almost doubled risk of total mortality CV mortality and major coronary events when combined with FRS.  
- Many men would move to a lower risk category, while more women would move from a lower to a higher risk category.  

**Study Type:** Prospective  
**Size:** n=18 cohorts, n=44,752 pts  
**Inclusion Criteria:** Dataset including ABI measurement and FRS data points, follow-up for mortality and CV events.  
**Exclusion Criteria:** Hx CHD, invalid ABI, not vital status follow-up.  
**1st Endpoint:** C index (fraction of occasions where the predictor score correctly predicts the earlier event for a pair of individuals) and NRI score  
**Results:**  
- C index for major coronary events, FRS only: Men: 0.67; 95% CI: 0.6–0.74; Women: 0.58; 95% CI: 0.49–0.66  
- CV mortality: Men: 0.68; 95% CI: 0.63–0.74; Women: 0.45; 95% CI: 0.38–0.52.  
- Adding ABI to FRS improves men’s scores modestly and women’s scores substantially. Major coronary events: Men: 0.69; 95% CI: 0.61–0.76; Women: 0.069; 95% CI: 0.61–0.076.  
- CV mortality: Men: 0.71; 95% CI: 0.65–0.76; Women: 0.65; 95% CI: 0.58–0.72  
- Prediction NRI scores: Major coronary events: ABI+FRS model led to improved performance mainly in women. Restricting to those at intermediate risk resulted in higher NRIs in both men and women.

### GETABI study
**Study type:** Prospective cohort study  
**Size:** n=6,880 pts; 5,392 pts=no PAD; 836 pts=asx PAD; 593 pts=sx PAD  
**Inclusion criteria:** Age ≥65 y, 5 y follow-up data, mentally competent to cooperate and sign consent  
**Exclusion criteria:** Life expectancy <6 mo  
**1st endpoint:** Severe vascular events, CV and all-cause mortality.  
**Results:**  
- Mortality (pts/1000):  
  - No PAD: 19.5; Asx PAD: 41.7;  
  - HR vs. no PAD: 1.66; 95% CI: 1.38–2.0;  
  - Sx PAD: 53.0;  
  - HR vs. no PAD: 1.89; 95% CI: 1.55–2.30.  
- No significant differences between asx and sx PAD groups in all-cause mortality.  
- Composite outcome All-cause mortality and Vascular events (pts/1000):  
  - No PAD: 27.2, Asx PAD: 60.4;  
  - HR vs. no PAD: 1.81; CI: 1.53–2.14;  
  - Sx PAD 104.7; HR compared to no PAD: 2.66; 95% CI: 2.25–3.15.  
- Difference between PAD groups also significant (HR: 1.48; 95% CI: 1.21–1.80.  
- No differences between PAD groups in MI, stroke, peripheral amputation. Sig differences in myocardial and peripheral revascularizations.

### USPSTF Review
Lin JS, et al. 2013(30)  
**Study type:** Systematic Evidence Review  
**Size:** n=1 meta-analysis, 18 population-based cohorts (52,510 pts)  
**Inclusion criteria:** 3 mo follow-up; designed to evaluate treatment benefit in screen-detected persons or populations who had Asx or unrecognized PAD  
**Exclusion criteria:** Pts with DM  
**Results:**  
- ABI added to other risk predictors increases but questions clinical utility or significance.  
- No randomized studies showing improved outcomes in response to detection of Asx disease.  
- Benefit of reclassification including ABI may be higher and clinically important in older populations at higher risk. May be most useful for pts near the thresholds of risk categories.  
- Acknowledge the evidence demonstrating increased morbidity and mortality in Asx pts.

© American Heart Association, Inc. and American College of Cardiology Foundation
<table>
<thead>
<tr>
<th>Study type: Systematic Review</th>
<th>Inclusion criteria: Studies reporting results of screening for axS pts</th>
<th>1° endpoint: Multiple that would justify screening for axS pts: Accurate test available; disease sufficiently prevalent and mortal; screening leads to reduced morbidity and mortality; screening is not harmful</th>
<th>Results:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Size: n=40 individual studies, 2 systematic reviews, 1 meta-analysis</td>
<td>Exclusion criteria: Not original data, did not report on axS pts</td>
<td></td>

</tbody>
</table>

- ABI is adequate test (diagnostic accuracy=0.87; diagnostic OR: 15.33; 95% CI: 9.39–25.02; pooled sensitivity=75%; specificity=86%);
- PAD is prevalent (average screening yield=17.2%) and mortal (pooled HR=2.99 for all-cause mortality and 2.35 for CV mortality).
- No studies compared screened vs. non screened populations for mortality outcomes.
- ABI screening can improve FRS in risk prediction.
- Some evidence that screening can lead to improved morbidity
- Little evidence about potential harm or cost-effectiveness.
- Discussed potential bleeding risk of ASA with no proven benefit
- Yield of ABI screening text in axS pts depends on prevalence of traditional risk factors
- No high quality evidence supports 'pt-important' benefits from screening low-risk individuals
- High-risk individuals may not need screening since there is already indication to treat their risk

<table>
<thead>
<tr>
<th>Study type: Prospective</th>
<th>Inclusion criteria:</th>
<th>1° endpoint: Development of CV events/mortality, clinical PAD (assessed every 6 mo). Median follow-up 9.37 y.</th>
<th>Results:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Size: n=2,797 pts</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

- Age 70–79 y
- No disability
- No functional limitation
- Baseline ABI measurement

- Self-reported Hx of claudication
- LEX revascularization

- CHD Death:
  - Men: HR: 4.38; 95% CI: 1.8–10.6;
  - Women HR: 4.96; 95% CI: 1.53–16.01.

- Incident PAD:
  - Men: HR:7.85; 95% CI: 4.44–13.90;
  - Women: HR: 5.56; 95% CI: 2.44–12.67.

- Stroke:
  - Men: HR: 1.17; 95% CI: 0.56–2.47;
  - Women: HR:2.58; 95% CI: 1.35–4.92;

- Incident MI:
  - Men: HR:2.26; 95% CI: 1.19–4.30;
  - Women: HR: 2.55; 95% CI: 1.13–5.72

- Other points:
- Subclinical PAD seems to affect women disproportionately compared to men
- Higher prevalence of borderline ABI in women; associated with poor outcomes
- Category of ABI >1.3; associated with poorer CV outcomes in women

Exclusion Criteria:
- Respiratory symptoms
- N/A
- Direct (to angiosome) vs. indirect infrapopliteal revascularization
- N/A
- Absence of ulcer

Results:
- Higher for TcPO2 than SaO2 pulse oximetry
- Correlation of TBI and SPP
- Wound healing and limb salvage, mortality
- Ability to determine PAD with systolic pressure assessment
- Clinical correlation
- Relationship of toe pressure to healing

- Laser Doppler SPP do not know if any had ulcers or rest pain
- 26 with ulcer or gangrene leading to amputation
- 13% with high ABI
- SPP correlates with ABP, TBP and TcPO2
- TcPO2 did not work well to predict healing
- Marginal quality
- Description of case detail included
- Aim: to test whether addition of the measurements of toe PW, which depend on distal perfusion, to pressure measurements could improve the determination of the severity of arterial disease and the presence of CLI.
- Toe pressure >30 mm Hg associated with good healing potential

suspected arterial disease had a normal resting ABI

Shishehbor MH, et al. 2016(71) 26860642

**Study type:** Observational

**Size:** n=237 pts; 40 pts with available TBI

**Inclusion criteria:**
- Pts in the IN.PACT DEEP Trial
- Isolated infrapopliteal disease
- Available ABI

**1st endpoint:** Diagnostic measurement of ABI and TBI to diagnose lower extremity ulcers and severe disease

**Results:** 1/3 of pts with CLI and severe isolated infrapopliteal disease have normal or incompressible ABIs. Only a few pts met the hemodynamic criteria for CLI according to cutoffs suggested for ABI (6%) and ankle pressure (16%) defined by multiple guidelines.

- Current recommended hemodynamic pressures to diagnose CLI are insensitive and failed to identify a significant portion of pts with lower extremity ulcers and angiographically proven severe disease. Toe pressure is more sensitive in pts with CLI.

ABI indicates ankle-brachial index; AHA, American Heart Association; asx, asymptomatic; CLI, critical limb ischemia; DM, diabetes mellitus; ICC, intraclass correlation coefficient; ICD, International Classification of Disease; N/A, not applicable; PAD, peripheral artery disease; PVD, peripheral vascular disease; PVR, pulse volume recordings; PW, pulse wave; RCT, randomized controlled trial; Sa O2, oxygen saturation; SDP, segmental Doppler pressure; SPP, skin perfusion pressure; sx, symptomatic; TBI, toe-brachial index; TBP, toe blood pressure; and TcPO2, transcutaneous oxygen pressure.

**Evidence Table 6. Nonrandomized Trials, Observational Studies, and/or Registries of Imaging for Anatomic Assessment (Ultrasound, CTA, MRA, Angiography)–Section 3.3.**

| Joshi SB, et al. 2009(82) 20083076 | Study type: NR (retrospective)  
Size: n=37 pts | Inclusion criteria: Consecutive pts requiring evaluation of aortoiliofemoral anatomy prior to cardiovascular procedures (pts being considered for percutaneous aortic valve intervention.)  
Exclusion criteria: N/A | 1st endpoint: Conventional angiographic and CT images were analyzed independently to assess suitability for large bore (7 mm diameter) intra-arterial catheter access.  
Results: Excellent CT image quality was achieved in 34 of 37 pts (92%). The mean contrast dose for CT was 12±2 mL. In 9 pts (24%), CT changed the assessment of femoral access feasibility. Furthermore, in another 7 pts (19%), unfavorable anatomy as shown by CT directed the avoidance of a particular side. Overall, CT findings altered the interventional approach in 16 pts (43%). | Purpose was to evaluate the feasibility of using ultra-low-dose intra-arterial contrast injection for iliofemoral CT angiography to follow diagnostic cardiac catheterization.  
• 0 to 15 mL of contrast diluted with normal saline was injected intra-arterially via the pigtail catheter while a spiral CT of the abdomen and pelvis was acquired  
• There was no significant deterioration detected in renal function after coronary and CT angiography (estimated glomerular filtration rate 54.8±3.8 mL/min before vs 53.3±3.9 mL/min after, p=0.55). |
| Mesurolle B, et al. 2004(83) 15246474 | Study type: NR (prospective)  
Size: n=16 pts | Inclusion criteria: In the assessment of occlusive arterial disease of abdominal aorta and the lower extremities.  
Exclusion criteria: N/A | 1st endpoint: Sensitivity and specificity vs. catheter angiography  
Results: Overall sensitivity of helical CT was 91% and specificity 93%. Segmental analysis found a sensitivity of 43% in infrapopliteal arteries, and a specificity of 86%. Helical CT was inconclusive in 6.2% of segments whereas angiography was inconclusive in 5%. Overall sensitivity of helical CT was 91% and specificity 93%. Segmental analysis found a sensitivity of 43% in infrapopliteal arteries, and a specificity of 86%. | 16 pts underwent both transcatheter angiography and helical CT |
| Romano M, et al. 2004(84) 15145492 | Study type: NR (prospective)  
Size: n=42 pts | Inclusion criteria: Untreated pts with peripheral vascular occlusive disease  
Exclusion criteria: Pts with previous radiological interventions or surgery for their peripheral vascular occlusive disease | 1st endpoint: Sensitivity and specificity of 4 channel MDCTA of the abdominal aorta and lower extremities arteries compared with DSA.  
Results: Overall sensitivity and specificity of MDCTA were 93 and 95%, respectively, with positive and negative predictive values of 90 and 97%. Overall diagnostic accuracy was 94%. Normal arterial | N/A |
segments and 100% occlusions were correctly identified in all cases by MDCTA. Moderately stenotic segments interpretation in the calves appeared to be more controversial, but no statistical difference in accuracy of MDCTA in the infrapopliteal district arteries was noted with respect to accuracy in the more proximal arterial bed. Good to excellent interobserver and intraobserver agreement were observed, with k values greater than 0.80.

**Study type:** NR (prospective)

**Inclusion criteria:** Pts referred for DSA of the lower extremities for investigation of sx atherosclerotic disease of the legs

**Exclusion criteria:** Elevated serum creatinine (>120 micro mol/L) levels, allergy to contrast material, or acute limb-threatening ischemia were excluded. Because pts under-went MDCT angiography and DSA on different days, potential candidates who lived more than 1 H from our hospital were not asked to enroll.

**1st endpoint:** Sensitivity and specificity of MDCT angiography in showing arterial occlusions and stenoses of ≥75%. Intertechnique agreement was measured for each anatomic segment, and interobserver agreement was calculated for both techniques. Agreement was quantified using the kappa statistic.

**Results:** The sensitivity and specificity of MDCT angiography for depicting arterial occlusions and stenoses of at least 75% were 88.6% and 97.7%, and 92.2% and 96.8%, respectively. Substantial intertechnique agreement (kappa >0.4) was present in 102 (97.1%) of 105 arterial segments. Substantial interobserver agreement was present in 104 (99.0%) of 105 comparisons for both MDCT angiography and DSA with an average kappa value of 0.84 for CT and 0.78 for DSA. MDCT angiography showed more patent segments than DSA (1,192 vs. 1,091). All 9 segments seen on DSA and not seen on MDCT angiography were in the calves. Of 110 segments seen on MDCT angiography and not seen on DSA, 100 (90.9%) were in the calves.

**Study type:** A review of the evidence base for the adverse effects associated with radiographic contrast drugs.

**Inclusion criteria:** N/A

**Exclusion criteria:** N/A

**1st endpoint:** N/A

**Results:**
- Monitor renal functions for contrast-induced nephropathy
- Nephrotoxic meds should be discontinued before contrast administration
- Either nonionic iso-osmolar contrast media or

**Important side effects include hypersensitivity reactions, thyroid dysfunction and contrast-induced nephropathy**

**The knowledge and screening of side effects can allow appreciation and then prompt management.**
nonionic low-osmolar contrast media use to be favored
- Lowest dose to be used
- Fluid intake to be encouraged.
- In high-risk pts N-acetylcysteine may be administered.

**Size**: n=328 pts having a vascular intervention for PAD, AAA, or carotid disease | **Inclusion criteria**: Intervention for 1 of the PVD territories. Poly vascular disease defined as disease in ≥2 territories.  
**Exclusion criteria**: N/A | 1st endpoint: Prevalence of AAA, CAD, and carotid disease in PAD pts receiving revascularization  
Results: Poly-vascular bed pts had about 8X the risk of carotid disease or AAA. | • Looks at the risk according to multiple vascular beds not just PAD  
• Can’t discern the risk of AAA or CVD with PAD alone |
| Kurvers HA, et al. 2003(95) 12764269 | **Study type**: Cross-sectional single center study  
**Size**: n=2,274 vascular pts | **Inclusion criteria**: Enrolled in SMART study referred to a vascular center with sx peripheral atherosclerosis in some arterial territory or elevated risk factors (e.g. DM)  
**Exclusion criteria**: N/A | 1st endpoint: Prevalence of carotid stenosis  
Results: Prevalence 12.5% in PAD pts vs. ~2% for risk factor only pts. Age >54 y and PAD increased prevalence to 22%. | • Select sx atherosclerosis population |

AAA indicates abdominal aortic aneurysm; ABI, ankle-brachial index; CAD, coronary artery disease; CVD, cardiovascular disease; DM, diabetes mellitus; PAD, peripheral artery disease; pt, patient; PVD, peripheral vascular disease; sx, symp.

Evidence Table 12. Nonrandomized Trials, Observational Studies, and/or Registries for Renal Artery Disease—Section 4.4.
### Exclusion criteria

- N/A

### Results

- 834 (96%) were technically adequate to define the presence or absence of RVD
- Prevalence of RAS was 6.8%.
- No difference in prevalence between white and black pts.

### Evidence Table 13. RCTs Evaluating Antiplatelet Agents—Section 5.1.

| POPADAD Belch J, et al. 2008(16) 18927173 | Aim: To determine whether ASA and antioxidant therapy, combined or alone, are more effective than placebo in reducing the development of cardiovascular events in pts with DM and axSx PAD. Study type: Multicenter, randomized, double blind, 2x2 factorial, placebo controlled trial. **Size:** n=1,276 pts | **Inclusion criteria:** Aged ≥40 y with type 1 or type 2 DM and an ABI of ≤0.99 but no sx cardiovascular disease **Exclusion criteria:** People with evidence of sx CV disease; those who use ASA or antioxidant therapy on a regular basis; those with peptic ulceration, severe dyspepsia, a bleeding disorder, or intolerance to ASA; those with suspected serious physical illness (such as cancer), which might have been expected to curtail life expectancy; those with psychiatric illness (reported by their GP); those with congenital heart disease; and those unable to give informed consent | **Intervention and comparator:** Daily, 100 mg ASA tablet + antioxidant capsule (n=320), ASA tablet + placebo capsule (n=318), placebo tablet + antioxidant capsule (n=320), or placebo tablet + placebo capsule (n=318) | **1º endpoint:**  
- Death from coronary heart disease or stroke, nonfatal MI or stroke, or amputation above the ankle for CLI; and death from CHD or stroke  
- 116 of 638 primary events occurred in the ASA groups compared with 117 of 638 in the no ASA groups (18.2% vs. 18.3%) HR: 0.98; 95% CI: 0.76–1.26. 43 deaths from coronary heart disease or stroke occurred in the ASA groups compared with 35 in the no ASA groups (6.7% vs. 5.5%): HR: 1.23; 95% CI: 0.79–1.93).  
- No difference in treatment for ABI <0.90 | **Adverse effect (effect estimates):**  
- Malignancy 0.76 (0.52–1.11),  
- Gastrointestinal bleeding, 0.90 (0.53–1.52)  
- Dyspepsia 0.77 (0.55–1.08),  
- Allergy 1.14 (0.80–1.63) |
### Fowkes FG, et al. 2010(15) 20197530

**Aim:** To determine the effectiveness of ASA in preventing events in people with a low ABI identified on screening the general population.

**Study type:** Randomized Controlled Trial

**Size:** n=3,350 pts

**Inclusion criteria:** Age 50 to 75 with no Hx of vascular disease and ABI <0.95

**Exclusion criteria:**
- Hx of MI, stroke, angina, or PAD; currently used ASA, other antiplatelet or anticoagulant agents; had severe indigestion; had chronic liver or kidney disease; were receiving chemotherapy; had contraindications to ASA; and had an abnormally high or low hematocrit value (measured after the screening)

**Intervention:** 100 mg enteric coated ASA

**Comparator:** Placebo

**1st endpoint:** Composite of initial (earliest) fatal or nonfatal coronary event or stroke or revascularization

No statistically significant difference was found between groups (13.7 events per 1000 person-years in the ASA group vs. 13.3 in the placebo group; HR: 1.03; 95% CI: 0.84–1.27)

**Safety endpoint:**
- Major hemorrhage
- Initial event of major hemorrhage requiring admission to hospital occurred in 34 pts (2.5 per 1000 person-years) in the ASA group and 20 (1.5 per 1000 person-years) in the placebo group (HR: 1.71; 95% CI: 0.99–2.97).

### CLIPS Catalano M, et al. 2007(104) 17305650

**Aim:** To assess the prophylactic efficacy of ASA and a high-dose antioxidant vitamin combination in pts with PAD in terms of reduction of the risk of a first vascular event (MI, stroke, vascular death) and CLI.

**Study type:** Randomized, placebo-controlled, double-blind clinical trial with 2x2 factorial designs.

**Size:** n=366 pts

**Inclusion criteria:** stage I–II PAD documented by angiography or ultrasound, with ankle/brachial index <0.85 or toe index <0.6

**Exclusion criteria:**
- Fontaine stage III or IV PVD; life expectancy <24 mo; vascular surgery or angioplasty in the last 3 mo;
- Pregnancy or lactation;
- Contraindication to ASA;
- Major cardiovascular events requiring antiplatelet therapy;
- Participation in another clinical trial;
- Uncooperative pts;
- Treatment with drugs that interfere with hemostasis, such as anticoagulants, antiplatelet agents and prostanoids, peripheral vasodilators, ASA and/or other drugs that interfere with hemostasis

**Intervention and Comparator:** Oral ASA (100 mg daily), oral antioxidant vitamins (600 mg vitamin E, 250 mg vitamin C and 20 mg beta-carotene daily), both or neither

**1st endpoints:**
- Incidence of fatal and nonfatal vascular events (MI, stroke and pulmonary embolism) and critical leg ischemia
- 7 of 185 ASA and 20 of 181 placebo pts suffered a major vascular event (risk reduction 64%, p=0.022)
- 5 ASA and 8 placebo pts, respectively, suffered critical leg ischemia (total 12 vs. 28, p=0.014)

**Safety endpoint:** Incidence of bleeding 4 in ASA and 0 in placebo (p=0.99)

- All initial vascular events, defined as a composite of a primary endpoint event or angina, IC or transient ischemic attack; no statistically significant difference between groups (22.8 events per 1000 person-years in the ASA group vs. 22.9 in the placebo group; HR: 1.00; 95% CI: 0.85–1.17)
- All-cause mortality no significant difference in all-cause mortality between groups (176 vs. 186 deaths, respectively; HR: 0.95; 95% CI: 0.77–1.16)

- All initial cardiovascular events, defined as a composite of death or nonfatal coronary event, stroke or revascularization
- No statistically significant difference was found between groups (20 (1.5 per 1000 person-years) in the ASA group and 28 (1.7 per 1000 person-years) in the placebo group (HR: 1.71; 95% CI: 0.99–2.97).

</table>
**Aim:** To assess the relative efficacy of clopidogrel (75 mg once daily) and ASA (325 mg once daily) in reducing the risk of a composite outcome cluster of ischemic stroke, MI, or vascular death

**Study type:** Randomized, blinded

**Size:** n=19,185 pts

**Inclusion criteria:** Pts with atherosclerotic vascular disease manifested as either recent ischemic stroke, recent MI, or sx PAD

**Exclusion criteria:**
- Age <21 y
- Severe cerebral deficit likely to lead to pt being bedridden or demented
- Carotid endarterectomy after qualifying stroke
- Qualifying stroke induced by carotid endarterectomy or angiography
- Pt unlikely to be discharged alone after qualifying event
- Severe comorbidity likely to limit pt's life expectancy to less than 3 y
- Uncontrolled hypertension
- Scheduled for major surgery
- Contraindications to study drugs:
  - Severe renal or hepatic insufficiency
  - Hemostatic disorder or systemic bleeding
  - Hx of haemostatic disorder or systemic bleeding
  - Hx of thrombocytopenia or neutropenia
  - Hx of drug-induced hematologic or hepatic abnormalities
  - Known to have abnormal WBC, differential, or platelet count
  - Anticipated requirement for long-term anticoagulants, non-study antiplatelet drugs or NSAIDs affecting platelet function
  - Hx of ASA sensitivity
  - Women of childbearing age not

**Intervention:** Clopidogrel 75 mg per d

**Comparator:** ASA 325 mg per d

**1° endpoint:**
- Composite outcome cluster of ischemic stroke, MI, or vascular death
- 1960 first events included in the outcome cluster on which an intention-to-treat analysis showed that pts treated with clopidogrel had an annual 5.32% risk of ischemic stroke, MI, or vascular death lower than 5.83% with ASA (p=0.043). A relative-risk reduction of 8.7% in favor of clopidogrel (95% CI: 0.3–16.5)

**Safety endpoint:** Bleeding similar in the 2 groups

- Reported adverse experiences in the clopidogrel and ASA groups judged to be severe included rash (0.26% vs. 0.10%), diarrhea (0.23% vs. 0.11%), upper gastrointestinal discomfort (0.97% vs. 1.22%), intracranial hemorrhage (0.33% vs. 0.47%), and gastrointestinal hemorrhage (0.52% vs. 0.72%), respectively. There were 10 (0.10%) pts in the clopidogrel group with significant reductions in neutrophils (<1.2 × 10^9/L) and 16 (0.17%) in the ASA group.
- Marginally statistically significant result (p=0.043) was observed for the primary endpoint, with statistical heterogeneity of treatment effect (p=0.042) being observed between the 3 predefined subgroups of pts with recent stroke, MI, or PVD. Only the PVD subgroup clearly benefited from clopidogrel over ASA the use of clopidogrel vs. ASA.
using reliable contraception
Currently receiving investigation drug
• Previously entered in other clopidogrel studies
Geographic or other factors making study participation impractical

**CHARISMA**  
Cacoub PP, et al. 2009(108) 19136484

**Aim:** To determine whether clopidogrel + ASA provides greater protection against major cardiovascular events than ASA alone in pts with PAD.

**Study type:** Substudy of Bhatt et al., 2007. Post hoc analysis of pt subgroup from a larger randomized trial

**Size:** n=3,096 pts

**Inclusion criteria:** Sx (2,838) current IC together with an ABI ≤0.85, or a Hx of IC together with a previous related intervention (amputation, surgical or catheter-based peripheral revascularization) or sx (258) PAD ABI, 0.90 were identified among those with multiple risk factors

**Exclusion criteria:** Taking oral antithrombotic medications or NSAIDs on a long-term basis (although cyclooxygenase-2 inhibitors were permitted). Pts were also excluded if, in the judgment of the investigator, they had established indications for clopidogrel therapy (such as a recent acute coronary syndrome). Pts who were scheduled to undergo a revascularization were not allowed to enroll until the procedure had been completed; such pts were excluded if they were considered to require clopidogrel after revascularization.

**Intervention:** Clopidogrel + ASA  
**Comparator:** Placebo + ASA

**1° endpoint:** Among the pts with PAD, the primary endpoint occurred in 7.6% in the clopidogrel + ASA group and 8.9% in the placebo + ASA group (HR: 0.85; 95% CI: 0.66–1.08; p=0.18). In these pts, the rate of MI was lower in the dual antiplatelet arm than the ASA alone arm: 2.3% vs. 3.7% (HR: 0.63; 95% CI: 0.42–0.96; p=0.029), as was the rate of hospitalization for ischemic events: 16.5% vs. 20.1% (HR: 0.81; 95% CI: 0.68–0.95; p=0.011).

**Safety endpoint:** The rates of severe, fatal, or moderate bleeding did not differ between the groups, whereas minor bleeding was increased with clopidogrel: 34.4% vs. 20.8% (OR: 1.99; 95% CI: 1.69–2.34; p<0.001)

**Positive subgroup within negative trials are often the result of confounding or bias, especially post-hoc defined subgroups.**

**The rate of the primary safety endpoint (severe bleeding) was 1.7% in each treatment group (p 1⁄4 0.90).**

---

**CHARISMA**  
Bhatt DL, et al. 2007(109) 17498584

**Aim:** To determine whether there is benefit of clopidogrel + ASA in a subpopulation of CHARISMA

**Inclusion criteria:** “CAPRIE-like” if they were enrolled with a documented prior MI, documented prior ischemic stroke, or sx PAD

**Exclusion criteria:**

**Intervention:** Clopidogrel + ASA  
**Comparator:** Placebo + ASA

**1° endpoint:** The rate of cardiovascular death, MI, or stroke was significantly lower in the clopidogrel + ASA arm than in the placebo + ASA arm: 7.3% vs. 8.8% (HR 0.83; 95% CI: 0.72–0.96; p=0.01)

**Positive subgroups within negative trials are often the result of confounding or bias, especially post hoc defined subgroups.**

**Hospitalizations for**
(Clopidogrel for High Atherothrombotic Risk and Ischemic Stabilization, Management, and Avoidance) trial, where no statistically significant benefit was found in the overall broad population of stable pts studied.

**Study type:** Post hoc analysis of pt subgroup from a larger randomized trial  

**Size:** n=9,478 pts

- Taking oral antithrombotic medications or NSAIDs on a long-term basis (although cyclooxygenase-2 inhibitors were permitted).
- In the judgment of the investigator, pts had established indications for clopidogrel therapy (such as a recent acute coronary syndrome).
- Pts who were scheduled to undergo a revascularization were not allowed to enroll until the procedure had been completed; such pts were excluded if they were considered to require clopidogrel after revascularization.

**Safety endpoint:**
- Moderate bleeding was significantly increased: 2.0% vs. 1.3% (HR: 1.60; 95% CI: 1.16–2.20; p=0.004).
- No significant difference in the rate of severe bleeding: 1.7% vs. 1.5% (HR: 1.12; 95% CI: 0.81–1.53; p=0.50)

| 2014(121)  
| 25262270 | **Aim:** Investigate the efficacy and safety of vorapaxar in NSTE ACS pts with documented PAD  
**Study type:** Subgroup of large randomized trial  
**Size:** n=936 pts | **Inclusion criteria:** TRACER pts with a hx of PAD  
**Exclusion criteria:** TRACER pts without PAD | **Intervention:** Vorapaxar  
**Comparator:** Placebo | 1° **endpoint:** Lower rates of ischemic endpoints, peripheral revascularization, and amputation with vorapaxar did not reach statistical significance.*  
**Safety endpoint:** Vorapaxar increased bleeding in both pts with and without PAD at a similar magnitude of risk. | N/A |
| **Katsanos K, et al.**  
| 2015 (122)  
| 26274912 | **Aim:** Comparative Efficacy and Safety of Different Antiplatelet Agents for Prevention of Major Cardiovascular Events and Leg Amputations in pts with PAD  
**Study type:** Meta-analysis  
**Size:** n=34,518 pts | **Inclusion criteria:** RCT using antiplatelet drugs in pts with PAD  
**Exclusion criteria:** N/A | **Intervention:** Antiplatelet therapy  
**Comparator:** Placebo | 1° **endpoint:** MACE and leg amputations  
A significant MACE reduction was noted with Ticagrelor plus aspirin (RR: 0.67; 95%CrI: 0.46–0.96; NNT=66), Clopidogrel (RR: 0.72; 95%CrI: 0.58–0.91; NNT=80), Ticlopidine (RR: 0.75; 95%CrI: 0.58–0.96; NN=87), and Clopidogrel plus aspirin (RR: 0.78; 95%CrI: 0.61–0.99; NNT=98).  
Dual antiplatelet therapy with Clopidogrel plus aspirin significantly reduced major amputations following leg revascularization (RR: 0.68; 95%CrI: 0.46–0.99 compared to ASA, NNT=94)  
**Safety endpoint:** The risk of severe bleeding was significantly higher with Ticlopidine (RR: 5.03; 95%CrI: 1.23–39.6; NNH=25), Vorapaxar (RR: 1.80; 95%CrI: 1.22–2.69; NNH=130), and Clopidogrel plus ASA (RR: 1.48; 95%CrI: 1.05-2.10; NNT=215) | N/A |
| **Magnani G, et al.**  
| 2015(123)  
| 25792124 | **Aim:** To observe the safety and efficacy of vorapaxar  
**Study type:** Multinational, double-blinded, placebo-controlled TRA 2°P-TIMI 50 trial | **Inclusion criteria:**  
- Met TRA 2°P-TIMI 50 inclusion criteria  
- Hx of spontaneous MI within prior 2 wk to 12 mo  
- Those with symptomatic PAD had hx of IC in conjunction with either an ABI <0.85 or previous revascularization for limb ischemia | **Intervention:** Vorapaxar sulfate 2.5 mg (vorapaxar 2.08 mg) daily  
**Comparator:** Placebo | 1° **endpoint:** Composite endpoints of CV death, MI, or stroke, and CV death, MI, stroke, or recurrent ischemia leading to urgent coronary revascularization  
• 3 y KM event rate of CV death, MI, or stroke was 7.9% in vorapaxar compared with 9.5% in placebo (HR: 0.80; 95% CI: 0.73–0.89; p<0.001).  
• 3 y KM event rate of CV death, MI, stroke, or  
- Vorapaxar was shown to reduce CV death, MI, or stroke in the intended use and FDA approved population (not those with a hx of stroke). | N/A |
| Size: n=16,897 pts | Exclusion criteria: N/A | urgent coronary revascularization was 10.1% in vorapaxar and 11.8% in placebo (HR: 0.83; 95% CI: 0.76–0.90; p<0.001).  
- 3 y KM event rate of CV death or MI was 7.2% in vorapaxar and 8.3% in placebo; HR: 0.83; 95% CI: 0.75–0.93, p<0.001).  
- 3 y KM event rate of MI was 5.4% in vorapaxar and 6.4% in placebo (p<0.001)  
- 3 y KM event rate of stroke was 1.2% in vorapaxar and 1.6% in placebo (p=0.002) individually.  
Safety endpoint: GUSTO moderate or severe bleeding:  
- Combined bleeding criteria was 3.7% with vorapaxar and 2.4% in placebo (HR, 1.55; 95% CI: 1.30–1.86, p<0.001).  
- Severe bleeding was 1.3% with vorapaxar vs. 1.0% with placebo (HR 1.24; 95% CI: 0.92–1.66, P=0.16) |

Berger JS et al, 2009 (124)  
**Aim:** To determine the effect of ASA on CV event rates in pts with PAD  
**Study type:** Meta-analysis of prospective RCTs  
**Size:** n=18 trials, 5,269 pts  
**Inclusion criteria:**  
- Prospective RCTs  
- PAD pts assigned to aspirin or placebo/control group  
- Data on all-cause mortality, CV death, MI, stroke, and major bleeding  
**Exclusion criteria:** N/A  
**Intervention:** ASA  
**Comparator:** Placebo/control  
**1º endpoint:**  
- Nonfatal MI, nonfatal stroke, CV death  
- Secondary outcomes were all-cause mortality  
**Safety endpoint:** Major bleeding  
- ASA therapy, alone or in combination with dipyridomole, had no significant effect on CV events  
- ASA did have significant reduction in nonfatal stroke  
- No significant outcome for MI, CV mortality, or all-cause mortality

ABI indicates ankle-brachial index; ACS, acute coronary syndrome; ALI, acute limb ischemia; ASA, aspirin; CHD, coronary heart disease; CI indicates confidence interval; CLI, critical limb ischemia; CV, cardiovascular; GP, general practitioner; GUSTO, Global Utilization of Streptokinase and t-PA for Occluded; Coronary Arteries HR, hazard ratio; IC, intermittent claudication; IV, intravenous; KM, Kaplan-Meier; MACE, major adverse cardiac event; MI, myocardial infarction; N/A, not applicable; NNT, number needed to treat; NS, not significant; NYHA, New York Heart Association; NSAIDs, nonsteroidal anti-inflammatory drugs; OR, odds ratio; PAD, peripheral artery disease; PTA, percutaneous transluminal angioplasty; pt, patient; PVD, peripheral vascular disease; RCT, randomized controlled trial; RR, relative risk; and TLR, target lesion revascularization.

### Mohler ER, et al. 2003 (127) 12952839

**Aim:** Determine whether cholesterol lowering with atorvastatin improves walking performance in pts with IC

**Study type:** Prospective, blinded, RCT

**Size:** n=354 pts

**Inclusion criteria:**
- Age >25 y
- Stable IC for 6 mo
- ABI ≤0.90
- 20% reduction in ABI post exercise (Gardner)
- LDL ≤160.

**Exclusion criteria:**
- MI, coronary revascularization, peripheral revascularization within 6 mo.
- USA within 3 mo.
- Stroke or TIA within 6 mo.
- DVT/PE within 3 mo.
- Current engagement in exercise rehab program.

**Intervention:**
- Atorvastatin 10 mg daily (120 pts)
- Atorvastatin 80 g daily (120 pts)

**Comparator:** Placebo (114 pts)

**1st endpoint:** Change in MWT at 12 mo.
- Placebo: 50±12 s
- Atorva 10: 90±18 s
- Atorva 80: 90±18 s (p=0.37)

**Safety endpoint:** PTs with CAD or other indication for lipid lowering therapy.

### ICPOP

**Hiatt WR, et al. 2010 (128) 20212073

**Aim:** Test the hypothesis that ER Niacin plus lovastatin would improve exercise performance in pts with PAD and claudication compared with diet intervention.

**Study type:** RCT

**Size:** n=387

**Inclusion criteria:**
- Age >40 y
- Stable IC
- ABI ≤0.90
- 20% reduction in ABI post-exercise (Gardner)
- LDL ≤160
- PWT 1–20 min
- <20% variability in 2 assessments.

**Exclusion criteria:** Pt's with CAD or other indication for lipid lowering therapy.

**Intervention:** Low-dose Niacin 1000 mg plus lovastatin 40 mg or high-dose Niacin 2000 mg plus lovastatin 40 mg

**Comparator:** Diet

**1st endpoint:** Change from baseline in PWT and in claudication onset time at 28 wk
- Diet: 26.5%; 95% CI: 16.4%–37.6%
- Low Niacin/Lova: 38.6%; 95% CI: 27.6%–50.6%, p=0.096
- High Niacin/Lova: 37.8%; 95% CI: 26.6%–50.1%, p=0.137

**Safety endpoint:** 2/3 of pts in each treatment group reported drug-related adverse event (pruritis, diarrhea, elevated blood sugar). Flushing in 54%. Serious adverse events were

<td>Intervention: Oral pioglitazone (15 mg qd mo 1; 30 mg mo 2; 45 qd mo 3-end; medication could be adjusted if needed) Comparator: Placebo 1° endpoint: Composite all-cause mortality, nonfatal MI, stroke, ACS, coronary or peripheral revascularization, major amputation</td>
<td>2° endpoint: • All-cause mortality, non–fatal MI, stroke HR: 0.84; 95% CI: 0.72–0.98; p=0.027 • Subgroup analysis for PAD not reported. Summary: • Primary endpoint was negative, but secondary endpoint (primary for most studies of MACE) positive for reduction in events with pioglitazone vs. placebo; no PAD specific data presented, though 20% of pt population had sx PAD • PAD substudy (2009 publication): PAD subset had higher event rates than non-PAD subset. In subset of pts enrolled with PAD (N=1,274 reported), there was no benefit of pioglitazone on the primary or secondary endpoint with increased rate of LE revascularization in the pioglitazone vs. placebo groups (p=0.0077). In the subgroup of pts randomized WITHOUT PAD, there was a beneficial effect of pioglitazone seen.</td>
</tr>

</table>

**Evidence Table 22. Nonrandomized Trials, Observational Studies, and/or Registries of Glycemic Control–Section 5.5.**

ABI indicates ankle-brachial index; ACS, acute coronary syndrome; ALT, alanine aminotransferase; CAD, coronary artery disease; CHF, congestive heart failure; CI, confidence interval; CKD, chronic kidney disease; CLI, critical limb ischemia; DM, diabetes mellitus; HR, hazard ratio; HgB, hemoglobin; LE, lower extremity; MACE, medical adverse cardiac events; MI, myocardial infarction; NYHA, New York Heart Association; PAD, peripheral artery disease; pt, patient; RCT, randomized controlled trial, and ULN, upper limit of normal.
**Study type:** Observational cohort study vs. retrospective chart review (study design not clear) at a single center

**Size:** n=278 pts; 197 pts with DM

**Inclusion criteria:** Pts with PAD undergoing PTA for CLI including pts with and without DMs

**Exclusion criteria:** Pts with CLI who were not candidates for PTA and treated by other means

**1° endpoint:** Major amputation, mortality (all-cause)

**Results:** Average follow-up 90±72 wk.

Among 287 CLI pts with DM:
HgB A1c level not associated with increased mortality
HgBA1c level associated with major amputation, adjusted HR: 1.349 per 1% increment; 95% CI: 1.103–1.650; p=0.004)

Association was robust after MV adjustment for other factors.

Increased quartiles of HgB A1c had stepwise increase in risk for major amputation, adjust HRs (for Fontaine Stage IV, dialysis, infection)

</table>

- Another observational study providing some support for adequate glycemic control among PAD pts with DM with CLI who will undergo revascularization (pre-procedural HgB A1c) to reduce risk of amputation---association more pronounced for highest quartile of HgB A1c vs. lowest quartile.
- No mortality benefit seen over a relatively short period of follow-up

**Study type:** Observational cohort study

**Size:** n=4,549 in entire cohort; 1,974 with DM without prior lower extremity amputation

**Inclusion criteria:** Native Americans age 45–74 y seen for baseline examination 1989–1992 and subsequent follow-up visits

**Exclusion criteria:** Pts without DM; those with prior LE amputation excluded

**1° endpoint:** Incident lower extremity amputation

**Results:** After average 8 yr follow-up. Among pts with PAD (ABI <0.9), higher HgB A1c increased odds of lower extremity amputation. Relationship also seen among pts with normal ABI and those with non-compressible vessels (ABI >1.4).

Odds of incident LE amputation among pts with DM and PAD (ABI <0.9) or non-compressible vessels (ABI ≤1.4); reference pts with DM with normal ABI and Hgb A1c <6.5%* (OR=1)

Antonicelli R, et al. 1999(169) 10492316

Aim: Evaluate the efficacy of low-dose, subcutaneous calcium heparin in comparison with placebo in pts with IC

Study type: RCT

Size: n=201 pts

Inclusion criteria: • Willingness to use parenteral therapy • ≥6 mo Hx of IC who had PAD confirmed by Doppler examination

Exclusion criteria: N/A

Intervention: Subcutaneous heparin and ASA

Comparator: ASA alone

1° endpoint: • Maximum walking time 40% in heparin group and 16% in placebo group (p=0.05) • Pain-free walking time 39% in heparin group and 23% in placebo group (p=0.09).

Summary: • Treatment with low-dose subcutaneous heparin is safe and effective in improving walking performance

ASA indicates acetylsalicylic acid; CI, confidence interval; HR, hazard ratio; IC, intermittent claudication; MI, myocardial infarction; N/A, not applicable; PAD, peripheral artery disease; PTFE, polytetrafluoroethylene; pt, patient; and RCT, randomized controlled trial.

| Bedenis R, et al. 2014 (173) 25358850 | **Aim:** To determine Cilostazol’s impact on claudication walking distances, mortality, and vascular events in pts with stable IC.  
**Study type:** Meta-analysis: Double-blind, RCTs of cilostazol vs. placebo, or vs. other antiplatelet agents in pts with stable IC.  
**Size:**  
• n=15 studies.  
• n=3,718 pts | **Inclusion criteria:** Cilostazol with placebo, or medications currently known to increase walking distance e.g. pentoxifylline. All pts had IC secondary to PAD. | All included studies compared cilostazol 100mg 2x/d with placebo. In addition, 2 studies compared cilostazol 50 mg 2x/d with placebo, and 1 study compared cilostazol 150 mg 2x/d with placebo. 3 studies compared cilostazol 100 mg 2x/d with pentoxifylline 400 mg 3x/d. 1 study compared cilostazol 100 mg 2x/d with pentoxifylline 600 mg 2x/d and 1 study compared cilostazol 100 mg 2x/d with the antiplatelet K-134 50 mg and 100mg 2x/d | For 8 studies data were compatible for comparison by meta-analysis, but data for 7 studies were too heterogeneous to be pooled. For the studies included in the meta-analysis, for ICD there was an improvement in the cilostazol group for the 100 mg and 50 mg 2x/d, compared with placebo (WMD: 31.41 meters; 95% CI: 22.36–40.45 meters; p=0.00001) and (WMD: 19.89 meters; 95% CI: 9.44–30.34 meters; p=0.0002), respectively. ICD was improved in the cilostazol group for the comparison of cilostazol 150 mg vs. placebo and cilostazol 100 mg vs. pentoxifylline, but only single studies were used for these analyses. ACD was significantly increased in pts taking cilostazol 100 mg and 50 mg 2x/d, compared with placebo (WMD: 43.12 meters; 95% CI: 18.28–67.96 meters; p=0.0007) and (WMD: 32.00 meters; 95% CI: 14.17–49.83 meters; p=0.0004), respectively. As with ICD, ACD was increased in pts taking cilostazol 150 mg vs. placebo, but with only 1 study an association cannot be clearly determined. 2 studies comparing cilostazol to pentoxifylline had opposing findings, resulting in an imprecise CI (WMD: 13.42 meters (95% CI: -43.51 – 70.35 meters; p=0.64). ABI was lowered in the cilostazol 100 mg group compared with placebo (WMD: 0.06; 95% CI: 0.04–0.08; p=0.00001). The single study evaluating ABI had opposing findings, resulting in imprecise CIs. | There was no association between treatment type and all-cause mortality for any of the treatment comparisons, but there were very few events, and therefore inadequately powered. In general cilostazol was associated with a higher odds of headache, diarrhea, abnormal stool, dizziness and palpitations |

| **Dawson DL, et al. 2000 (174) 11063952** | **Aim:** To determine evaluate the relative efficacy and safety of cilostazol and pentoxifylline.  
**Study type:** Randomized, double-blind, placebo-controlled, multicenter trial.  
**Size:** n=698 pts | **Inclusion criteria:**  
- Moderate-to-severe claudication  
- Baseline pain-free walking distance ≥53.6 m  
- Baseline maximal walking distance ≤537.6 m | **Study intervention:** Pentoxifylline or cilostazol  
**Comparator:** Placebo | **Primary endpoint:** Walking ability, measured by MWD.  
- Cilostazol treatment resulted in greater MWD than both pentoxifylline and placebo at 24 wk (p<0.001).  
- Pentoxifylline treatment resulted in no improvement in MWD compared to placebo.  
**Secondary endpoints:** PFWD and resting Doppler limb pressures  
- At wk 4 and after, there was a greater improvement in PFWD with cilostazol treatment than placebo (p<0.01)  
- There was no difference in PFWD with pentoxifylline treatment compared with placebo (p<0.05). | | | |
| **Goldenberger NA, et al. 2012 (175) 22615190** | **Aim:** To investigate the effect of cilostazol + L-carnitine vs. cilostazol alone on treadmill performance in IC.  
**Secondary objectives:** To evaluate QoL measures and safety indices with the drug | **Inclusion criteria:** PAD pts with stable IC were randomized to either L-carnitine 1 g or matching placebo 2x/d, on a background of cilostazol.  
- 145 pts met criteria for the mITT population and 120 pts for the per-protocol population. 74 L-carnitine/71 placebo. | | | | | |
**Study type:** A multicenter, randomized, double-blind, placebo-controlled trial  
**Size:** n=164 pts  

In the cilostazol/l-carnitine group, the mean increase in physical functioning on the SF-36v2 was also nearly double that of the cilostazol/placebo group (6.77 [16.379] vs. 3.73 [17.566], respectively; p=0.066).

| Warner CJ, et al. 2014 (176) | **Aim:** MEDLINE (1946-2012), and Cochrane CENTRAL (1996-2012), and trial registries searched for studies comparing cilostazol in combination with antiplatelet therapy to antiplatelet therapy alone after PVI.  
**Study type:** Meta-analysis:  
**Size:** n=1,522 pts |
|---|---|
| **Inclusion criteria:**  
- Pts undergoing endovascular treatment (angioplasty or stenting) for infrainguinal LE PVD.  
- The intervention must be cilostazol in the periprocedural setting.  
- The comparison group may be no cilostazol, an antiplatelet medication, or placebo.  
- ≥6 mo follow-up  
- The study reported at ≥1 prespecified outcome of interest (restenosis, freedom from amputation, mortality).  
- 2 RCTs and 4 retrospective cohorts met inclusion criteria. 1,522 pts included in the review. A majority (87%) were from retrospective cohort studies.  
- All studies were conducted in Japan and published between 2008–2012.  
- All compared cilostazol with either no cilostazol (n=4) or an alternative antiplatelet medication (n=2), with both groups receiving various co-interventions (ASA with or without an adjunct antiplatelet medication). |
| The addition of cilostazol was associated with decreased restenosis (RR: 0.71; 95% CI: 0.60–0.84; p<0.001), improved amputation-free survival (HR: 0.63; 95% CI: 0.47–0.85; p=0.002), improved limb salvage (HR: 0.42; 95% CI: 0.27–0.66; p<0.001), and improved freedom from target lesion revascularization (RR: 1.36; 95% CI: 1.14–1.61; p<0.001).  
There was no significant reduction in mortality among those receiving cilostazol (RR: 0.73; 95% CI: 0.45–1.19; p=0.21). |
**STOP-IC**

Iida O, et al. 2013 (177) 23652861

**Aim:** To determine by angiographic follow-up whether treatment with cilostazol reduces restenosis at 12 mo after PTA with provisional nitinol stenting for femoropopliteal disease

**Inclusion criteria:** Within 1 wk after randomization, each pt was admitted and underwent PTA with provisional nitinol stenting.

**Study intervention:** 75 in cilostazol

**Study comparator:** 77 placebo

**Results:** During the 12 mo follow-up period, 11 pts died and 152 pts (80%) had evaluable angiographic data at 12 mo. The angiographic restenosis rate at 12 mo was 20% (15/75) in the cilostazol group vs. 49% (38/77) in the noncilostazol group (p=0.0001) by ITT analysis.

The cilostazol group also had a significantly higher event-free survival at 12 mo (83% vs. 71%, p=0.02), although cardiovascular event rates were similar in both groups.

| FLUVACS Gurfinkel EP, et al. 2004 (183) 14683739 | Aim: To test the effect of 1 yr benefit of influenza vaccination in pts with MI and planned PCI  
Study type: RCT  
Size: n=301 (200 MI pts and 101 PCI pts) | **Inclusion criteria:** MI pts or PCI pts  
**Exclusion criteria:** Unstable CAD, prior by-bass surgery, angioplasty, or tissue necrosis | **Intervention:** Influenza vaccine (151)  
**Comparator:** No vaccination on top of standard medication (150) | 1° endpoint: Time to first CVD  
- At 6 mo: 2% in vaccinated intervention group vs. 8% CVD in unvaccinated controls (RR: 0.25; 95% CI: 0.07–0.86; p=0.01)  
- At 1 yr: 6% in vaccinated intervention group vs. 17% CVD in unvaccinated controls. (RR: 0.34; 95% CI: 0.17–0.71; p=0.002)  
2° endpoint: Time to first composite triple endpoint of CVD, MI, and rehospitalization for severe recurrent ischemia at 1 yr was significantly decreased in the intervention group compared to control group (22% in vaccinated intervention group vs. 37% in unvaccinated control group; RR: 0.59; 95% CI: 0.4–0.86; p=0.004)  
- Reduction in RR of CVD in vaccinated group at 1 y.  
- No PAD specific evidence identified | |
| FLUCAD Ciszewski A, et al. 2008 (184) 18187561 | Aim: Determine effects of influenza vaccination on coronary events in pts with CAD  
Study type: RCT  
Size: n=658 treated CAD pts (477 men) | **Inclusion criteria:**  
- Age 30–80 y  
- CAD confirmed by angiography with ≥50% stenosis of ≥1 large epicardial coronary artery  
**Exclusion criteria:** Congestive heart failure NYHA III/IV  
- Planned CV surgery within 6mo  
- Evolving renal failure  
- Neoplastic disease  
- Psycho-organic disorder or any factor impeding follow-up | **Intervention:** Influenza vaccine (325)  
**Comparator:** Placebo (333) | 1° endpoint:  
- 1 yr CVD  
- At 1 y: HR: 1.06; 95% CI: 0.15–7.56; p=0.95  
2° endpoint:  
- No difference between two groups for CVD, acute MI, or coronary revascularization  
- At 1 yr coronary ischemic events was decreased in intervention group compared to placebo control group (HR: 0.54; 95% CI: 0.29–0.99; p=0.047)  
**Limitations:** Small sample size, effect of flu vaccination on restenosis is unknown, pt selection bias  
- No PAD specific evidence identified |

**Behavioral approach, can improve functional performance compared with a control group in pts with PAD with and without IC.**

**Study type:** RCT

**Size:** n=194 pts

**Evidence of PAD.**

**Exclusion criteria:** LE amputation, wheelchair confinement, inability to walk 50 ft, walking aid except cane, walking impairment other than PAD, surgery within past 3 mo, other major comorbidities that would preclude unsupervised exercise

**Intervention:** pts without IC, walk at 12–14 on Borg RPE scale. Using a group-mediated cognitive behavioral approach, exercisers also met once a wk for 90 min.

**Comparator:** Health education control group that met weekly for 60 min to discuss general health topics.

**Safety endpoint:** 1 exerciser developed dyspnea on exertion and subsequently required CABG and completed study after recovery.

**1st endpoint:** WIQ speed score increased (from 36.1–46.5 in exercisers vs. 34.9–36.5 in the control group; mean difference: +8.8; 95% CI: +1.6–+16.1; p=0.018). Change in the WIQ distance score was not different between groups at 12 mo (p=0.139).

**Safety endpoint:** No adverse events reported

**1st endpoint:** WIQ speed score increased (from 36.1–46.5 in exercisers vs. 34.9–36.5 in the control group; mean difference: +8.8; 95% CI: +1.6–+16.1; p=0.018). Change in the WIQ distance score was not different between groups at 12 mo (p=0.139).

**Safety endpoint:** No adverse events reported

**1st endpoint:** For the exercise and control groups, respectively, average walking speed scores increased by 5.7 (standard error: 2.2) units and decreased by 1.9 (standard error: 2.8) units (p=0.03); the mental health QoL subscale score of the SF-36 increased by 3.2 (standard error: 2.8) units (p<0.001).

<td>ERASE Fakhry F, et al. 2015 (196) 26547465</td>
<td>To assess the 1 y effectiveness of combination therapy of ER + SET or SET alone in pts with IC</td>
<td>ABI &lt;0.9 or decrease &gt;0.15 with exercise, 1 or more vascular stenosis at the aortoiliac or femoropopliteal level or both, and impaired MWD.</td>
<td>Combination therapy of ER + SET. For ER, a stent was used only if the initial balloon angioplasty was not successful. SET was started 2–4 wk after ER. SET consisted primarily of intermittent bouts of treadmill walking to near-maximum claudication pain. Frequency of 2–3 sessions for 30–45 min for initial 3 mo followed by at least 1 session per wk between mo 3–6 and then 1 session per 4 wk until 1 y.</td>
<td>After 1 y, MWD increased in both groups (p&lt;0.001) with a greater improvement in the combined therapy group (p&lt;0.001). Similarly, ABI at rest and after exercise showed significantly greater improvement in the combination therapy group. Also, measures of health-related QoL improved in both groups with greater improvements with combined therapy.</td>
<td>Safety endpoint: See secondary outcomes. No study specific adverse events discussed.</td>
<td></td>
</tr>
</tbody>
</table>

- 21 pts (7%) withdrew, of whom 8 were in the SET group, 3 were in the PTA group, and 10 were in the combined group. 11 pts who had PTA had restenosis but none required revascularization.

- A higher proportion of pts without an additional intervention in the combination group (92%) vs. the SET alone (77%), HR: 3.2; 95% CI: 1.1–9.2; p=0.005.
### Guidon M and McGee H 2013 (197) 22804715

**Aim:** To assess the 1 y effects of participation in a 12 wk supervised exercise program on functional capacity and QoL for PAD pts

**Study type:** RCT

**Size:** n=44 pts

**Inclusion criteria:**
- Fontaine Stage II, ABI <0.9 at rest or a decrease of ankle pressure by ≥15 mm Hg post-exercise
- Exclusion criteria:
  - Comorbidities which precluded participation in exercise, MI past 6 mo,
  - acute onset or within one mo of IC, lower limb revascularization past 6 mo

**Intervention:**
- 2 d/wk supervised exercise for 12 wk. 30–40 min of aerobic exercise using a range of equipment including treadmill, stepper, elliptical trainer, recumbent cycle, and arm cycle. Intensity of 70%–80% of exercise test maximum HR. On treadmill, walking to leg pain of 3 of 4, rest, and resume walking. Exercise intensity progressed by increasing resistance or time.

**Comparator:** SET alone.

**1º endpoint:** At 12 wk, there was a trend towards improved QoL in both groups, with a tendency for greater improvement in the exercise group (p=0.066) and a trend towards improved functional capacity (WIQ Stair-climbing p=0.093) in the exercise group, with an increase of 8.55 points in the exercise group and a decrease of 13.42 points in the control group.

At 1 y, IC Questionnaire scores in the exercise group were considerably better than those in the control group, 27.94±19.83 vs. 38.54±24.26 (p=0.058), reflecting improved QoL and maintenance of benefits.

**Safety endpoint:** Not specified.

2 exercisers and 1 control dropped for progression of PAD, 3 exercisers dropped for non-specified medical reasons in first 12 wk.

---

### Gardner AW, et al. 2014 (198) 25237048

**Aim:** To compare the 12 wk effects of exercise training using a step watch home-exercise program, a supervised exercise program,

**Intervention:**
- 3 mo of intermittent walking (NEXT STEP) o mild-to-moderate claudication pain 3 d/wk, progressing from 20–45 min/session. Pts used step monitor during each session. Exercise logs

**Comparator:** Usual care, general advice about exercise and smoking cessation, ABI measurement

**1º endpoint:** At 12 wk, change scores for COT (p<0.001), PWT (p<0.001, 6 min walk distance (p=0.028), daily average cadence (p=0.011) were different among the 3 groups, with both walking programs showing changes in these

- Time to minimum calf muscle StO2 during exercise (p=0.025), large-artery elasticity index (p=0.012), and high-sensitivity C-reactive protein (p=0.041) were also significantly different among the 3 groups. Both walking groups improved time to minimum StO2. Only the NEXT Step home group had

| FAST Krankenberg H, et al. 2007 (226) 17592075 | **Aim:** SFA PTA vs. PTAS  
**Study type:** RCT  
**Size:** n= 244 pts | **Inclusion criteria:** SFA stenosis and claudication or CLI  
**Exclusion criteria:**  
- TL that required pretreatment with adjunctive devices, e.g., lasers or debulking catheters  
- A TL that extended into the popliteal artery; previous stent implantation in the targeted SFA  
- Multiple lesions >10 cm in length  
- Acute or subacute (≤4 wk) thrombotic occlusion  
- An untreated ipsilateral iliac artery stenosis  
- Ongoing dialysis treatment  
- Treatment with oral anticoagulants other than antiplatelet agents. | **Intervention:** PTAS  
**Comparator:** PTA  
**1st endpoint:** Technical success, 1 y duplex restenosis  
- For short lesions mean length 45 mm, no difference between PTAS and PTA  
- Overall, stent fractures were detected in 45 of 121 treated legs (37.2%). In a stent-based analysis, 64 of 261 stents (24.5%) showed fractures, which were classified as minor (single strut fracture) in 31 cases (48.4%), moderate (fracture of >1 strut) in 17 cases (26.6%), and severe (complete separation of stent segments) in 16 cases (25.0%). Fracture rates were 13.2% for stented length ≤8 cm, 42.4% for stented length >8–16 cm, and 52.0% for stented length >16 cm. In 21 cases (32.8%) there was a restenosis of >50% diameter reduction at the site of stent fracture. In 22 cases (34.4%) with stent fracture there was a total stent reocclusion. According to Kaplan Meier estimates, the primary patency rate at 12 mo was significantly lower for pts with stent fractures (41.1% vs. 84.3%, p<0.0001). |

ELA+PTA superior to PTA alone for SFA ISR  
Study enrollment was stopped at 250 pts due to early efficacy demonstrated at a prospectively-specified interim analysis. A total of 169 ELA+PTA pts (62.7% male; mean age 68.5±9.8 y) and 81 PTA pts (61.7% male; mean age 67.8±10.3 y) were enrolled. Mean lesion length was 19.6±12.0 cm vs. 19.3±11.9 cm, and 30.5% vs. 36.8% of pts exhibited total occlusion. ELA+PTA pts demonstrated superior procedural success (93.5% vs. 82.7%; p=0.01) with significantly fewer procedural complications. ELA+PTA and PTA pt 6-mo freedom from TLR was 73.5% vs. 51.8% (p<0.005), and 30 d major adverse event rates were 5.8% vs. 20.5% (p<0.001), respectively. ELA+PTA was associated with a 52% reduction in TLR (HR: 0.48; 95% CI: 0.31–0.74).

**1st endpoint:** Max treadmill time to onset of claudication at 6 mo follow-up p<0.01

- More PTA pt were asx on treadmill at 6 mo (p≤0.01)
- More PTA pt had no claudication at 6 mo (p≤0.05)
- ABI higher in PTA group at 6 mo (p≤0.05)
- Lower Nottingham Health Score pain scores at 6 mo in PTA group (p≤0.05)

| Whyman MR, et al. 1997(244) | **Aim:** 2 y follow-up of above study | **Inclusion criteria:**
- Unilateral IC
- Short stenoses

**Exclusion criteria:**
- Previous angioplasty or arterial surgery to the sx leg
- MI within 6 mo
- Pt taking oral anticoagulants

**Intervention:** PTA+medical therapy
**Comparator:** Medical therapy (Medical therapy=ASA+advise on smoking and exercise)

**1st endpoint:** Max treadmill time to onset of claudication at 2 y follow-up

**Safety endpoint:** Non-reported

- No difference in pt reported MWD, treadmill onset to claudication, treadmill MWD, or ABI (p>0.05)
- No difference in NHP QoL
| Perkins, JM, et al. 2011(245) 21855020 | **Aim:** Compare ABI and Walking distance in PAD pts treated with PTA vs. exercise training  
**Study type:** RCT  
**Size:** n=56 pts | **Inclusion criteria:** Unilateral claudication lesion(s) on angiography suitable for angioplasty, as agreed by surgeons and radiologists  
**Exclusion criteria:** Not specified in article | **Intervention:** PTA  
**Comparator:** Exercise training (Supervised exercise classes 2x/wk for the first 6 mo. After this, attendance was required on a regular basis according to the pt's progress. Each class lasted 30 min. Dynamic leg exercises were performed, with the intensity of exercise increasing as the pt's exercise tolerance improved. Pts were also encouraged to perform the same exercises at home on a regular basis) | **1st endpoint:** Better ABI in PTA group at 15 mo; no difference in ABI, distance to claudication or MWD at 6 y follow-up | • Small study  
• No difference in endpoints at 6 y follow-up (only 37 pts followed to 6 y)  
• PTA only (no stents or med Tx) |
| Spronk S, et al. 2009(246) 19188327 | **Aim:** To compare clinical success, functional capacity, and QoL during 12 mo after revascularization or supervised exercise training in pts with IC  
**Inclusion criteria:**  
• IC  
• Max PFWD <350 m  
• ABI <0.9  
**Exclusion criteria:**  
• AAA  
• Life incapacitating cardiac disease (≥NYHA class III) | **Intervention:** PTA with provisional stent  
**Comparator:** Hospital based supervised exercise training | **Safety endpoint:** Functional capacity defined in terms of ABI, maximum PFD, and MWD SF-36 QoL  
**1st endpoint:** Improvement in one Rutherford category | • At 1 wk endo superior  
• By 12 mo no difference  
• 2010 correction of statistical methods—better for exercise group—still no difference at 12 mo |

**Exclusion criteria:**
- AAA
- Life incapacitating cardiac disease (≥NYHA class III)
- Multilevel disease (i.e., same-side stenoses at both the iliac and femoral levels, requiring multiple revascularization procedures)
- Isolated tibial artery disease
- Lesions deemed unsuitable for revascularization (iliac or femoropopliteal TASC type D and some TASC type B and/or C lesions, such as a unilateral external iliac occlusion that involved the origins of the internal iliac and/or common femoral artery or single or multiple femoral popliteal lesions in the absence of continuous tibial vessels to improve inflow for a distal bypass procedure)
- Prior treatment for the lesion (including exercise training)

**Intervention:** PTA with provisional stent

**Comparator:** Hospital based supervised exercise training

**1<sup>st</sup> endpoint:** Mean improvement of health-related QoL and functional capacity over a 12 mo period, cumulative 12 mo costs, and incremental costs per QALY

**Safety endpoint:** Not reported

- Endo costs more than exercise program when adjusted for QALY however this study had no difference between QoL at 12 mo

### Inclusion criteria:
- PAD with sx unilateral claudication suitable for angioplasty and femoropopliteal lesions

### Exclusion criteria:
- Critical ischemia
- Incapacitating systemic disease
- Inability to tolerate treadmill testing
- Ischemic changes on ECG during treadmill testing
- Ipsilateral surgery/PTA in previous 6 mo

### Intervention:
- Endo+SE

### Comparator:
- Endo alone vs. SE alone
  - Endovascular therapy: Percutaneous transluminal angioplasty
  - Supervised exercise therapy: Circuit of exercises 3x/wk for 12 wk

### Concomitant therapy:
- All pts were prescribed antiplatelet therapy

### 1st endpoint:
- ICD, MWD, repeat revascular, peri-procedural complications

- No significant difference at 12 mo in ICD and MWD or QoL
Mazari FA, et al. 2010(195) 19762206

**Aim:** 3 mo data for above trial

**Study type:** RCT

**Size:** n=178 pts

**Inclusion criteria:** PAD with sx unilateral claudication suitable for angioplasty

**Exclusion criteria:**
- Critical ischemia
- Incapacitating systemic disease
- Inability to tolerate treadmill testing
- Ischemic changes on ECG during treadmill testing
- Ipsilateral surgery/PTA in previous 6 mo

**Intervention:** Endo+SE

**Comparator:**
- Endo alone vs. SE alone
- Endovascular therapy: Percutaneous transluminal angioplasty
  Supervised exercise therapy: Circuit of exercises 3 times per wk for 12 wk
- Concomitant therapy: All pts were prescribed antiplatelet therapy (ASA and/or clopidogrel), received smoking cessation advice and support (including nicotine replacement therapy and NHS smoking cessation program), and risk factor

**1st endpoint:** ICD, MWD, repeat revascular, peri-procedural complications

**Safety endpoint:** None reported

At 3 mo PTA + SEP provided greater improvement in claudication than SEP or PTA alone.
See above for 12 mo results
Nordanstig J, et al. 2011(255) 21397530

**Study type:** RCT multicenter

**Size:** Inv (n=100) vs. OMT(n=101)

| **Intervention:** | Invasive+OMT |
| **Comparator:** | OMT |
| | Revascularization: In general, aorto-iliac TASC A and B lesions were treated endovascularly and TASC C and D lesions with surgery. Femoropopliteal TASC A lesions were offered angioplasty, whereas TASC BeD lesions usually were treated surgically. For lesions in the common femoral artery, endarterectomy with or without patch angioplasty was used. |
| | Optimal medical therapy: ASA 75 mg daily (or ticlopidine if contraindication to ASA). Smokers were offered participation in a smoking cessation support program and received verbal and written information with smoking cessation advice. Hypertension, DM, and hyperlipidemia |

| **1st endpoint:** | 2 y Mean Walking Performance and QoL |

MWP was not significantly (p=0.104) improved in the INV vs. the NON group. 2 SF-36 physical subscales, Bodily Pain (p<0.01) and Role Physical (p<0.05) improved significantly more in the INV vs. the NON group. There were 7% crossovers against the study protocol in the INV group.

Study type: RCT (single center)  
Size: Invasive (n=79) vs. OMT (n=79) | IC >6 mo  
**Exclusion criteria:**  
- Very mild symptoms  
- Symptoms so severe that invasive treatment was considered mandatory (main criteria according to protocol: inability to work because of IC, subcritical ischemia with occasional rest pain, infrarenal aortic thrombosis)  
- Weight >120 kg (maximum possible load on treadmill)  
- ≥2 previously failed ipsilateral vascular interventions | Endo except for TASC D  
79 allocated to invasive Rx  
70 received intervention:  
- 52 pts Endovascular  
- 16 pts open surgery.  
- 2 pts hybrid | SF 36 (p<0.001) and VascularuQoL (p<0.01) at 12 mo better with Inv  
- Distance to onset of claudication better with Inv. Invasive (+124 m) vs. the noninvasive (+50 m) group (p=0.003)  
- No difference Inv vs. Meds for MWD change  
- Invasive therapy group included 18 pts treated with surgical and hybrid approach to invasive Rx  
- Outcomes not stratified by surgical vs. endovascular procedures.  
- Both aortoiliac and femoropopliteal disease pts were enrolled. Pragmatic design to include large IC population independent of whether surgical or endovascular approach was required | OMT |
| Malgor RD, et al 2015(257) 25721067 | Endo vs. surgical vs. SE vs. Meds | 
Study type: Meta-analysis of RCTs | RCTs of IC pts  
**Exclusion criteria:** Trials exclusively enrolling pts with CLI, defined as rest pain or tissue loss | Endo vs. surgical vs. SE vs. Meds | 
- Open surgery, endovascular therapy, and exercise therapy seemed to be superior to medical mgmt for walking distance, pain and claudication  
- Evidence is sparse supporting superiority of one of three approaches  
- Isolated iliac or femoropopliteal disease pts. may |
| **Size:** n=8 systematic reviews and 12 trials enrolling 1,548 pts | **Results:**  
RCTs for Surgery (with physical training):  
- Max. and symptom free walking distance improved vs. Medical management alone or exercise alone  
- ABI improved vs. surgery alone but not exercise  
- Endovascular approaches with medical mgmt. or exercise: Combination of both may be a better approach  
- Endovascular vs. open surgery:  
  - Studies generally showed open bypass had significantly longer hospital stay, high complications and a high 30-d mortality.  
  - Some SRs had conflicting info about 30-d mortality but patency was generally better in surgical arm.  
- Revasc with medical mgmt or exercise:  
  - Invasive revasc generally increased leg BP and flow parameters, better SF 36, overall QoL score and IC distance but not MWD  

**Safety endpoint:** Not reported |  
<p>|  | do better than combined disease according to the limited data. |</p>

| Scheinert D, et al. 2005 (261) 16653033 | Study type: Prospective series assessing SES fracture incidence | **Inclusion criteria:** PTAS for claudication or chronic ischemia. **Exclusion criteria:** None reported | **1st endpoint:**  
- Stent fracture incidence  
- Restenosis incidence  
**Results:** The primary patency rate at 12 mo was significantly lower for pts with stent fractures (41.1% vs. 84.3%, p<0.0001). | • Stent fractures predict restenosis  
• Overall, stent fractures were detected in 45 of 121 treated legs (37.2%). In a stent-based analysis, 64 of 261 stents (24.5%) showed fractures, which were classified as minor (single strut fracture) in 31 cases (48.4%), moderate (fracture of >1 strut) in 17 cases (26.6%), and severe (complete separation of stent segments) in 16 cases (25.0%). Fracture rates were 13.2% for stented length ≤8 cm, 42.4% for stented length >8–16 cm, and 52.0% for stented length >16 cm. In 21 cases (32.8%) there was a restenosis of >50% diameter reduction at the site of stent fracture. In 22 cases (34.4%) with stent fracture there was a total stent reocclusion. According to Kaplan Meier estimates, the primary patency rate at 12 mo was significantly lower for pts with stent fractures (41.1% vs. 84.3%; p<0.0001). |
| Sakamoto Y, et al. 2013 (262) 23536429 | Study type: Case series evaluating PTAS patency for SFA CTO | **Inclusion criteria:** SFA CTO undergoing PTAS. **Exclusion criteria:** None reported. Lack of CTO | **1st endpoint:** 5 y primary and secondary patency rates and the rates of freedom from bypass surgery, major or minor amputation, and all-cause death  
**Results:** Female gender (OR: 1.95; p=0.0051) and mean stent diameter | • Stent diameter predicts restenosis  
• Mean age was 72±9 y and 31% were female pts. In total, 58% of the pts had DM and 25% were pts with CLI. Occluded length was 194±89 mm, mean total stent length was 198±7 mm, and mean stent diameter was 7.1±0.9 mm. 5 y primary and secondary patency rates were 51.8% and 79.5%, respectively, and the rates of freedom from bypass surgery, major or minor |

Matsi PJ and Manninen HI 1998(270) 9853140

**Aim:** To report complications and predictors of complications in a cohort of pts undergoing endo revasc for claudication or CLI

**Study type:** Retrospective analysis

**Size:** n=410 procedures in 295 pts

**Inclusion criteria:** Pts undergoing peripheral intervention at a single center

**Exclusion:** None reported

**1° endpoint:** Complications and predictors of complications

**Results:** More complications in pts with occluded arteries compared to stenosed arteries; more bleeding complications in women; pts with CLI had higher mortality compared to claudication; mortality was driven by CAD and cerebrovascular disease

Limitation is that this is a single center retrospective analysis

| Jensen LP, et al. 2007(277) 17400486 | Aim: Compare PTFE and polyester grafts for femoral to above-knee popliteal artery bypass | Inclusion criteria:  
- Consecutive pts with chronic lower limb ischemia  
- Considered suitable for surgical revascularization using a supragenicular prosthetic bypass graft  
- Provided the pts consented to take part  
Exclusion criteria:  
- Age <18 y  
- Pregnant  
- Previously enrolled in the study  
- Considered impossible to follow  
- Informed consent could not be obtained. | Intervention: 6 mm Dacron conduit | 1° endpoint: 2 y primary patency rates for Dacron and PTFE were 70% and 57% (*p*=0.02), whereas the secondary patency rates were 76% and 65% (*p*=0.04), respectively. Primary patency at 2 y was significantly influenced by the number of patent crural vessels (2 or 3 67%, 1 50%, *p*=0.01). At 2 y, pts treated for CLI had a major amputation more often than pts operated on for IC, 10 and 3 respectively (*p*=0.003), and had higher mortality rates, 20% and 8% respectively (*p*=0.001). |
| | Study type: RCT (multi-center), Scandinavia | | Comparator: 6 mm PTFE conduit | Medical therapy was not standardized  
Amputations at 2 y, (major in 4% and minor in 3%), 30 d mortality and complications (wound infections: 3% and other wound complications: 13%) occurred equally frequent in both groups. |

| AbuRahma AF, et al. 1999(278) 10520903 | **Aim:** Compare patency of PTFE vs. saphenous vein grafts for above-knee bypass | **Inclusion criteria:**  
- Bilateral disabling claudication  
- Failed medical therapy  
- Long SFA occlusion with above-knee reconstitution. | **Intervention:** Pts received above-knee PTFE graft in 1 leg and saphenous vein graft in the other; were randomized in terms of the order of staged interventions (either SV-PTFE or PTFE-SV) | **Comparator:** Contralateral leg in same pts; each pt served as their own control | **1st endpoint:** No statistically significant differences between primary and secondary patency rates for both grafts; however, the assisted primary patency rates were higher for SVG (p<0.05). | Standardized antiplatelet therapy (ASA 325 mg), but no mention of other components of medical therapy. All PTFE were 8 mm grafts. |
| Green RM, et al. 2000(279) 10709052 | **Aim:** Identify factors affecting patency of prosthetic above-knee femoropopliteal bypass grafts | **Inclusion criteria:**  
- An angiographically demonstrated superficial femoral artery occlusion with reconstitution of a popliteal segment above the knee  
- Not undergone any earlier infrainguinal vascular procedures. | **Intervention:** Above-knee femoral-popliteal bypass | **Comparator:** Gore-tex vs. Hemashield grafts | **1st endpoint:** No difference in primary or secondary patency rates at 5 yrs between the 2 grafts. | Primary patency 45% vs. 43%. Secondary patency 68% vs. 68%. Risk of graft occlusion increased for pts age <65 d (HR: 2.1; p=0.001) and for grafts with diameters <7mm (HR: 1.65; p=0.0219). |
| Johnson WC and Lee KK 1999(280) 10587392 | **Aim:** To identify whether improved patency exists with different bypass graft materials for pts with femoral-popliteal above-knee bypass grafts. | **Inclusion criteria:** Pts scheduled for femoral-AK popliteal bypass grafting at 20 VA Medical Centers  
- Noncompressible vessels  
- ABI >0.9  
- Prior ipsilateral prosthetic fem-pop AK or below-knee bypass graft | **Intervention:** above-knee femoral-popliteal bypass graft. | **Comparator:** externally supported PTFE (n=265), HUV (n=261), or SV (n=270) | **1st endpoint:** The cumulative assisted primary patency rates were similar among the different conduit types at 2 yrs (SV: 81%; HUV: 70%; PTFE: 69%). After 5 y, above-knee SV bypass grafts had a significantly (p<0.01) better patency rate (73%) than HUV bypass grafts (53%), which had a possible bias against HUV and PTFE- pts with prior SV graft in ipsilateral leg were not excluded, but instead had randomization limited to either HUV or PTFE. |
### Aim: To compare vein with polytetrafluoroethylene for femoropopliteal bypasses with the distal anastomosis above the knee

**Study type:** RCT  
**Size:** n=151 bypasses (120 for claudication)

**Inclusion criteria:** Femoropopliteal bypass with the distal anastomosis to the popliteal artery above the knee

**Exclusion criteria:** Earlier arterial bypass graft procedure in the same leg or with the greater saphenous vein removed earlier.

**Intervention:** Femoral-AK popliteal bypass  
**Comparator:** Venous vs. PTFE graft conduit

**1st endpoint:** Primary patency rates after 5 yrs were 75.6% for venous bypass grafts and 51.9% for PTFE grafts (p=0.035). Secondary patency rates were 79.7% for vein and 57.2% for PTFE bypasses (p=0.036).

Reversed vein was used in 75 bypass grafts, and 6 mm stretched polytetrafluoroethylene prostheses were used 76 times.

---

### Aim: Compare patency of PTFE vs. saphenous vein for infra-inguinal arterial reconstructions

**Study type:** prospective, randomized, multicenter  
**Size:** n=845 bypasses. <20% of pts had claudication.

**Inclusion criteria:** Bypass to the popliteal or an infrapopliteal artery to control ischemia caused by atherosclerosis

**Exclusion criteria:**  
- Bypass for non-PAD diagnosis  
- Ability to treat with endovascular approach or through deep femoral revascularization without bypass  
- Sequential bypasses  
- Composite grafts  
- Inadequate vein

**Intervention:** PTFE  
**Comparator:** Autogenous saphenous vein graft

**1st endpoint:**  
- Patency and limb salvage by distal anastomotic site.  
- No difference in 4 y patency for above-knee grafts. No difference in rates of limb salvage for CLI.  
- 4 y primary patency for infrapopliteal bypasses were inferior for PTFE (49% vs. 12%, p<0.001).

Inadequate vein defined based on diameter <3.0 mm for graft to tibial artery or <4.0mm for graft to popliteal artery.

---

ABF indicates aortobifemoral bypass; ABI, ankle-brachial index; AK, above knee; BASI, bioabsorbable stent; CFA, common femoral artery; CFE, common femoral endarterectomy; CI indicates confidence interval; CFA, common femoral artery; CFE, common femoral artery endarterectomy; CLI, critical limb ischemia; EIA-external iliac artery; ENDO, endovascular interventions; ePTFE, expanded polytetrafluoroethylene; HR, hazard ratio; HUV, human umbilical vein; IC, intermittent claudication; MWD, maximum walking distance; N/A, not applicable; OR, odds ratio; PTA, percutaneous transluminal angioplasty; PTAS, percutaneous transluminal angioplasty stent; PTFE, polytetrafluoroethylene; pt, patient; RCT, randomized controlled trial.
Evidence Table 38. Nonrandomized Trials, Observational Studies, and/or Registries of Surgical Treatment for Claudication—Section 8.1.2.

| Werk M, et al. 2012(232) 23192918    | Aim: SFA DCB vs. PTA                   | Inclusion criteria: Sx femoro-popliteal atherosclerotic disease | Intervention: DCB Comparator: PTA                               | 1° endpoint: The primary endpoint was late lumen loss at 6 mo assessed by blinded angiographic corelab quantitative analyses | ● DEB is superior to PTA  
● Pts with sx femoro-popliteal atherosclerotic disease undergoing percutaneous transluminal angioplasty were randomized to paclitaxel-coated IN.PACT Pacific or uncoated Pacific balloons. The primary endpoint was late lumen loss at 6 mo assessed by blinded angiographic corelab quantitative analyses. Secondary endpoints were binary restenosis and Rutherford class change at 6 mo, and target lesion revascularization + major adverse clinical events (major adverse events=death, target limb amputation, or target lesion revascularization) at 6 and 12 mo. 85 pts (91 cases=interventional procedures) were randomized in 3 hospitals (44 to DEB and 47 to uncoated balloons). Average lesion length was 7.0±5.3 and 6.6±5.5 cm for DEB and control arm, respectively. Procedural success was obtained in all cases. 6 mo quantitative angiography showed that DEB were associated with significantly lower late lumen loss (-0.01 mm; 95% CI: -0.29–0.26 vs. 0.65 mm; 95% CI: 0.37–0.93; p=0.001) and fewer binary restenoses (3 [8.6%] vs. 11 [32.4%]; p=0.01). This translated into a clinically
Relevant benefit with significantly fewer major adverse events for DEB vs. uncoated balloons up to 12 mo (3 [7.1%] vs. 15 [34.9%]; p<0.01) as well as target lesion revascularizations (3 [7.1%] vs. 12 [27.9%]; p=0.02).

**IN.PACT**
Tepe G, et al. 2015(229) 25472980

**Aim:** SFA DCB vs. PTA  
**Study type:** RCT  
**Size:** n=331 pts  

**Inclusion criteria:** IC or ischemic rest pain attributable to superficial femoral and popliteal PAD  
**Exclusion criteria:**  
- Lesion and/or occlusions located in or extending to the popliteal artery or below the ankle joint space  
- Inflow lesion or occlusion in the ipsilateral iliac, SFA, or popliteal arteries with length ≥15 cm  
- Significant (>50% DS) inflow lesion or occlusion in the ipsilateral iliac, SFA, or popliteal arteries left untreated  
- Previously implanted stent in the TL(s)  
- Aneurysm in the target vessel. Acute thrombus in the TL  

**Intervention:** DCB  
**Comparator:** PTA  

**1st endpoint:** 12 mo primary patency  
- DCB superior to PTA  
- The IN.PACT SFA Trial is a prospective, multicenter, single-blinded, randomized trial in which 331 pts with IC or ischemic rest pain attributable to superficial femoral and popliteal PAD were randomly assigned in a 2:1 ratio to treatment with DCB or PTA. The primary efficacy endpoint was primary patency, defined as freedom from restenosis or clinically driven target lesion revascularization at 12 mo. Baseline characteristics were similar between the 2 groups. Mean lesion length and the percentage of total occlusions for the DCB and PTA arms were 8.94±4.89 and 8.81±5.12 cm (p=0.82) and 25.8% and 19.5% (p=0.22), respectively. DCB resulted in higher primary patency vs. PTA (82.2% vs. 52.4%; p<0.001). The rate of clinically driven target lesion revascularization was 2.4% in the DCB arm in comparison with 20.6% in the PTA arm (p<0.001). There was a low rate of vessel thrombosis in both arms (1.4% after DCB and 3.7% after PTA [p=0.10]). There were no device- or procedure-related deaths and no major amputations.

**ABSOLUTE**
Schillinger M, et al. 2007(225) 17502568

**Aim:** SFA PTAS vs. PTA  
**Study type:** RCT  
**Size:** n=104 pts  

**Inclusion criteria:** Rutherford 3–5 and SFA stenosis  
**Exclusion criteria:**  
- ALI  
- Previous bypass surgery, or stenting of the SFA  
- Untreated inflow disease of the ipsilateral pelvic arteries (>50% stenosis or occlusions)  

**Intervention:** PTAS  
**Comparator:** PTA  

**1st endpoint:** Restenosis by duplex at 2 y  
- PTAS is superior to PTA for long lesions (lesion length 112 mm PTAS and 93 mm PTA)  
- Of 104 pts with chronic limb ischemia and SFA obstructions, 98 (94%) could be followed up until 2 y after intervention for occurrence of restenosis (>50%) by duplex ultrasound and for clinical and hemodynamic outcome by treadmill walking distance and ABI. Restenosis rates at 2 y were 45.7% (21 of 46) vs. 69.2% (36 of 52) in favor of primary stenting compared with balloon angioplasty with optional secondary stenting by an ITT analysis (p=0.031). Consistently, stenting (whether primary or secondary; n=63) was superior to plain balloon angioplasty (n=35) with respect to the occurrence of restenosis (49.2% vs. 74.3%; p=0.028) by a treatment-received analysis. Clinically, pts in the primary stent group showed a trend toward better

<td></td>
<td>Overall, stent fractures were detected in 45 of 121 treated legs (37.2%). In a stent-based analysis, 64 of 261 stents (24.5%) showed fractures, which were classified as minor (single strut fracture) in 31 cases (48.4%), moderate (fracture of &gt;1 strut) in 17 cases (26.6%), and severe (complete separation of stent segments) in 16 cases (25.0%). Fracture rates were 13.2% for stented length ≤8 cm, 42.4% for stented length &gt;8–16 cm, and 52.0% for stented length &gt;16 cm. In 21 cases (32.8%) there was a restenosis of &gt;50% diameter reduction at the site of stent fracture. In 22 cases (34.4%) with stent fracture there was a total stent reocclusion. According to Kaplan-Meier estimates, the primary patency rate at 12 mo was significantly lower for pts with stent fractures (41.1% vs. 84.3%, p&lt;0.0001).</td>

| Kashyap VS, et al. 2008 (224) 18804943 | Study type: Retrospective Endo vs. ABF  
Size: n=189 pts | Inclusion criteria: Sx AIOD (claudication, 53%; rest pain, 28%; tissue loss, 12%; ALI, 7%)  
Exclusion criteria:  
- Pts undergoing endovascular treatment such as PTA or stenting for iliac stenoses  
- Pts with iliac dissection, an associated AAA, or iliac recanalization before or during AAA endograft placement. | 1st endpoint: Technical success, primary patency at 3 y  
Results: 3 y primary patency was higher in ABF group but population was biased | • ABF superior  
• Selection bias  
• The ABF pts were younger than the R/PTAS pts (60 vs. 65 y; p=0.003) and had higher rates of hyperlipidemia (p=0.009) and smoking (p<0.001). All other clinical variables, including cardiac status, DM, symptoms at presentation, TransAtlantic Inter-Society Consensus stratification, and presence of poor outflow were similar between the 2 groups. Pts underwent ABF with general anesthesia (96%), often with concomitant treatment of femoral or infrainguinal disease (61% endarterectomy, profundaplasty, or distal bypass). Technical success was universal, with marked improvement in ABI (0.48–0.84; p<0.001). Pts underwent R/PTAS with local anesthesia/sedation (78%), with a 96% technical success rate and similar hemodynamic improvement (0.36–0.82; p<0.001). At the time of R/PTAS, 21% of pts underwent femoral endarterectomy/profundaplasty or bypass (n=5) for concomitant infrainguinal disease. Limb-based primary patency at 3 y was significantly higher for ABF than for R/PTAS (93% vs. 74%, p=0.002). Secondary patency rates (97% vs. 95%), limb salvage (98% vs. 98%), and long-term |

ABI indicates ankle-brachial index; AFS, amputation-free survival; ALI, acute limb ischemia; BMS indicates bare metal stent; CD-TLR, clinically driven target lesion revascularization; CI, confidence interval; CLI, critical limb ischemia; DCB, drug coated balloon; DEB, drug eluting balloon; DES, drug eluting stent; DM, diabetes mellitus; HR, hazard ratio; IA-DEB, apmhirion-drug eluting balloon; IC, intermittent claudication; ISR, in stent restenosis; IQR, interquartile range; JACC, Journal of American College of Cardiology; LLL, late lumen loss; N/A, not applicable; OR, odds ratio; OS, overall survival; PAD, periphery artery disease; PCB, paclitaxel-coated balloon; PEB, paclitaxel eluting balloon; PTA, percutaneous angioplasty, PTAS, percutaneous angioplasty stent; pt, patient; RCT, randomized controlled trial; RR, relative risk; SES, self-expanding stents; and SFA, superficial femoral artery; and TL, target lesion.

### CRISP-US

**Ponec D, et al. 2004 (357)**

**Aim:** Compare SMART stent vs. Wallstent after suboptimal PTA.

**Study type:** RCT multicenter

**Size:** n=203 pts

**Inclusion criteria:** Chronic limb ischemia

**Exclusion criteria:** N/A

**Intervention:** Smart Stent

**Comparator:** Wall stent

**1st endpoint:** 9 mo composite end point rate was equivalent for the SMART stent and Wallstent (6.9% vs. 5.9%), with low rates of restenosis (3.5% vs. 2.7%), death (2.0% vs. 0.0%), and revascularization (2.0% vs. 4.0%) in the 2 groups. Primary patency at 12 mo was 94.7% and 91.1% with the SMART stent and Wallstent, respectively. Functional and hemodynamic improvement was also comparable between the groups. The frequency of major adverse events was similar at 1 y (4.9% vs. 5.9%).

**Second endpoint:**

The acute procedural success rate was higher in the SMART stent group (98.2% vs. 87.5%; p=0.002).

### CRISP-US

**Schillinger M, et al. 2006 (358)**

**Aim:** Primary Stent vs. Angioplasty

**Study type:** RCT multicenter

**Size:** n=104 pts

**Inclusion criteria:** Severe claudication or chronic limb ischemia due to stenosis or occlusion of the SFA

**Exclusion criteria:** N/A

**Intervention:** Self-expanding nitinol stent

**Comparator:** Angioplasty

**1st endpoint:** At 6 mo, the rate of restenosis on angiography was 24% in the stent group and 43% in the angioplasty group (p=0.05); at 12 mo the rates on duplex ultrasonography were 37% and 63%, respectively (p=0.01). Pts in the stent group were able to walk significantly farther on a treadmill at 6 and 12 mo than those in the angioplasty group.

Angiographic follow-up was not done in all pts, resulting in lack of quantitative data on lumen diameter, residual stenosis, etc.

### BASIL

**Adam DJ, et al. 2005 (328)**

**Aim:** Infrainguinal surgical bypass vs. PTA for CLI

**Study type:** RCT

**Size:** n= 452 pts

**Inclusion criteria:** CLI due to infrainguinal PAD

**Exclusion criteria:** N/A

**Intervention:** PTA (N=224)

**Comparator:** Bypass (N=228)

**1st endpoint:** Amputation free survival

**Safety endpoint:** Mortality

- **Equal outcomes**
- The trial ran for 5.5 y, and follow-up finished when pts reached an endpoint (amputation of trial leg above the ankle or death). 7 pts were lost to follow-up after randomization (3 assigned angioplasty, 2 surgery); of these, 3 were lost (1 angioplasty, 2 surgery) during the first y of follow-up. 195 (86%) of 228 pts assigned to bypass surgery and 216 (96%) of 224 to...
balloon angioplasty underwent an attempt at their allocated intervention at a median (IQR) of 6 (3–16) and 6 (2–20) d after randomization, respectively. At the end of follow-up, 248 (55%) pts were alive without amputation (of trial leg), 38 (8%) alive with amputation, 36 (8%) dead after amputation, and 130 (29%) dead without amputation. After 6 mo, the 2 strategies did not differ significantly in amputation-free survival (48 vs. 60 pts; unadjusted HR: 1.07; 95% CI: 0.72–1.6; adjusted HR: 0.73; 95% CI: 0.49–1.07). No difference in health-related quality of life between the 2 strategies, but for the first y the hospital costs associated with a surgery-first strategy were about 1/3 higher than those with an angioplasty-first strategy.

### PREVENT III
Conte MS, et al. 2006 (359) 16616230

**Aim:** Reduce stenosis in Surgical bypass for CLI using E2F decoy

**Study type:** Prospective, randomized, double blinded, phase III RCT

**Size:** n=1,404 pts

**Inclusion criteria:** Pts with CLI (R4-6) who had autologous vein graft randomized to placebo or E2F decoy

**Exclusion criteria:** IC, hypercoagulable state, revisions of infrainguinal bypass grafts

**Intervention:** PTA (N=517)

**Comparator:** Bypass (N=341)

**1st endpoint:** Nontechnical index graft failure resulting in revision or major amputation

**Safety endpoint:** All-cause graft failure, freedom from significant index graft stenosis, amputation, index graft failure survival, graft patency, and limb salvage

- 2.7% 30 d mortality
- 4.7% MI
- 5.2% early graft occlusion
- Primary patency at 1 y: 61%
- Primary assisted patency: 77%
- Secondary patency: 80%
- Limb salvage: 88%

### BEST-CLI
Farber A, et al. 2014 (360) 25241324

**Aim:** To compare best endovascular vs. best surgical therapy in pts with CLI. Compare treatment efficacy,

**Inclusion criteria:** Pts with CLI (R4-6)

**Exclusion criteria:** N/A

**Intervention:** Endovascular Tx (n=1,050)

**Comparator:** Bypass (N=1,050)

**1st endpoint:** MALE-free survival

**Safety endpoint:** MALE-POD (i.e., death within 30 d of procedure)

N/A
<table>
<thead>
<tr>
<th>Study type: A prospective, multicenter, RCT. CLI trial has a 2-cohort design. The first cohort (1,620 pts) evaluates outcomes in pts who have adequate single segment great saphenous vein. <td>Aim: To compare a collagen and oxidized cellulose dressing to moistened gauze with regards to wound healing. Study Type: RCT Size: n=276 pts</td>
</tr>
<tr>
<td>Inclusion criteria: ≥8 y of age with a diabetic foot ulcer ≥30 d duration, Wagner grade 1–2, and an area of ≥1 cm² (greatest length × greatest width). Pts had adequate circulation with an oscillometer reading of the limb that had the target wound of ≥1 U and a wound that was debrided of</td>
</tr>
<tr>
<td>Intervention: Promogran, a wound dressing consisting of collagen and oxidized regenerated cellulose for diabetic plantar ulcers. Comparator: Moistened Gauze with secondary dressing. 1st endpoint: ● Complete healing of the study ulcer (wound) ● After 12 wk of treatment, 51 (37.0%) Promogran treated pts had complete wound closure compared with 39 (28.3%) control pts, but this difference was not statistically significant (p=0.12). ● The difference in healing between Tx groups achieved borderline significance in the subgroup of pts with wounds of &lt;6 mo duration. In pts with ulcers &lt;6 mo duration, Limitations: Study did not standardize frequency of dressing changes.</td>
</tr>
</tbody>
</table>

- Freedom from perioperative death
- Freedom from MI
- Freedom from stroke, freedom from reinterventions (major and minor) in index leg, number of reinterventions (major and minor) per limb salvaged freedom from clinical failure
- Freedom from CLI
- Freedom from all-cause mortality
- Freedom from hemodynamic failure.
necrotic/nonviable tissue at enrollment.

**Exclusion criteria:**
- Clinical signs of infection
- A target wound that had exposed bone
- A concurrent illness or a condition that may have interfered with wound healing, known hypersensitivity to any of the dressing components
- Unwillingness or inability of an ambulatory pt to be fitted with appropriate shoe gear or an off-loading device
- Multiple diabetic ulcers on the same foot.

43 (45%) of 95 Promogran-treated pts healed compared with 29 (33%) of 89 controls ($p=0.056$). In the group with wounds <6 mo duration, similar numbers of pts healed in the Promogran (8/43 [19%]; $p=0.83$) groups. No differences were seen in the safety measurements between groups.

Study type: |

Inclusion criteria: CLI with rest pain, ulcers, or gangrene (Rutherford 4–6), who then required pedal bypass either as primary therapy or after prior endovascular

Intervention: Pedal Bypass post intervention. PEI

Comparator: Primary pedal bypass. BSF

1° endpoint:
- Overall, primary patency at 1 y was 58.3%, and secondary patency was 61.3%.

</tbody>
</table>
amputation prevention clinic from March 2012–July 2013. Pts at highest risk for limb loss, defined as ischemic wounds (ischemic ulcer or gangrene) or diabetic foot ulcers.

**Exclusion criteria:** New pts evaluated for benign conditions (e.g., arthritis, overuse injuries, simple infections in nondiabetics, venous ulcers, minor trauma, radiculopathy).

**Results:** 67% of wounds were present >6 wk before referral. A total of 151 podiatric and 86 vascular interventions were performed, with an equal distribution of endovascular and open revascularizations. Complete wound healing observed in 59% of wounds, and average time to full healing was 12 wk. Hindfoot wounds predictive of failure to heal (OR: 0.21; p<0.01; 95% CI: 0.06–0.68).

with limb threatening neuroischemic wounds. Hindfoot or ankle wounds can adversely influence the outcome. Healing can be prolonged and a substantial proportion of pts can be expected to have a recurrence, therefore surveillance is mandatory. A coordinated amputation prevention program may help to minimize hospital readmissions in the high-risk population.

| Fogarty TJ, et al. 1963 (390) 13945714 | Size: n=71 | Extremity arterial bypass reconstruction | **Results:**  
- Mean duration of symptoms was 43 h (median 24), and mean time from hospital presentation to the operating room was 36 h (median 12)  
- Death, limb loss, or both, were associated with a paralytic limb (p=0.001) and congestive heart failure (p=0.03) |
| Shin HS, et al. 2013 (377) 24436594 | Study type: Descriptive | Inclusion criteria: N/A | **Results:**  
- First description of embolectomy catheter |
| Eliason JL and Wakefield TW 2009 (391) 19298933 | Study type: Review article | Inclusion criteria: All pts with ALI | **Results:**  
- Compartment pressures are easily measured through multiple methods of pressure transduction  
- The majority of the lethal events associated with IR injury occur with acute lung injury as a prominent component of the multiple organ dysfunction syndrome |
| de Donato G, et al. 2014 (378) 24342067 | Study type: Single institution cohort | Inclusion criteria: All pts w ALI from graft thrombosis | **Results:**  
- Thromboembolectomy alone in 35%  
- 45.5% via CFA  
- 30 d mortality 4.4%  
- 15% in hospital complications  
- 8 pts with complication from catheter |
| Baril DT, et al. 2013 (379) 23714364 | Study type: Registry review | Inclusion criteria: All pts undergoing infrainguinal lower | **Results:**  
- ALI predictor of both major amputation  
- Age and gender similar to CLI  
- ALI less likely to be on ASA (63% vs. 75%; p<0.0001) or a statin (55% vs. 68%);
Size: \( n = 323 \) bypass procedures

extremity bypass between 2003 and 2011 (ALI vs. CLI)

Exclusion criteria: N/A

(HR: 2.16; CI: 1.38–3.40; \( p = 0.001 \)) and mortality

(HR: 1.41; CI: 1.09–1.83; \( p = 0.009 \) at 1 y)

\( p < 0.001 \)

- ALI more likely to be current smokers (49% vs. 39%; \( p < 0.0001 \)), to have had a prior ipsilateral bypass (33% vs. 24%; \( p = 0.004 \)) or a prior ipsilateral percutaneous intervention (41% vs. 29%; \( p = 0.001 \))

Lurie F, et al. 2015 (392) 25154566

Study type: Multiple institution review

Size: \( n = 1,074 \) pts

Inclusion criteria: Pts treated within 14 d of onset of their symptoms of nonembolic ALI

Exclusion criteria: Elective admission, no therapy

1\(^\circ\) endpoint: Clinical and technical outcomes, number and type of reinterventions, complications, relief of ischemia, limb salvage, and AFS

Results:
- No association between the choice of initial treatment, pt characteristics, location of the occlusion, or the class of ischemia, individually or in combination
- Combined endpoint of readmission and AFS was significantly lower in the CDT and CDTA groups
- The cause of ALI was an occluded native vessel in 115 pts (56.1%) and an occluded bypass graft in 90 (43.9%).
- Initial treatment resulted in an overall primary success of 67.3%. 60 pts (29.7%) required a second intervention, 11 (5.4%) required a third intervention, 5 (2.4%) required amputation, and 2 (1%) died

ALI indicates acute limb ischemia; AFS, amputation-free survival; ASA, acetylsalicylic Acid; CA, contrast arteriography; CDTA, catheter directed thrombolysis and angioplasty; CDT, catheter directed thrombolysis; CFA, common femoral artery; CI, confidence interval; CLI, critical limb ischemia; CTA, computed tomography angiography; DSA, digital subtraction angiography; DUAM, duplex ultrasound arterial mapping; HR, hazard ratio; MI, myocardial infarction; MRA, magnetic resonance angiography; N/A, not applicable; NEJM, New England Journal of Medicine; NIS, National Inpatient Sample; OR, odds ratio; pt, patient; and RR, relative risk.

Evidence Table 49. Nonrandomized Trials, Observational Studies, and/or Registries of Diagnostic Evaluation of the Cause of ALI–Section 9.2.2.

(There is no literature specifically addressing the diagnostic work up for the cause of ALI. This large single-center series does give etiologies. Echocardiography and telemetry seem reasonable for those without underlying PAD. Focused evaluation for hypercoagulable state seems reasonable in those with native artery thrombosis.)

**Exclusion criteria:** Pts with revascularization for CLI

- Compared to lesions <100 mm, longer lesions had higher failed primary patency (100–200 mm; HR: 2.0; p=0.16 vs. >200 mm: HR=2.6; p=0.03)
- Short and intermediate lesions had similar failed secondary patency (<5% incidence)
- Lesions >200 mm had higher trend in failed secondary patency (HR=4.2; p=0.06)
- Compared to lesions >100 mm, higher gain in long-term patency with outpatient surveillance and reintervention for longer lesions and significantly so for intermediate lesions (100–200 mm=23% vs. <100 mm=8%; p=0.041)

Percutaneous treatment of femoral artery lesions was lower for long lesions (>100mm).
- Outpatient surveillance for restenosis requiring repeat intervention had a greater effect on long-term patency in pts receiving initial treatment for longer femoral artery lesions (>100 mm length).

ABI indicates ankle-brachial index; AKV, above knee venous graft; BKV, below knee venous graft; CFDS, color flow duplex surveillance; CI, confidence interval; CLI, critical limb ischemia; DU, duplex ultrasound; FP, femoropopliteal graft; FT, femorotibial graft; GFV, graft flow velocity; HVC, high-velocity criteria; IC, intermittent claudication; LCV; MGV; NPV, negative predictive value; NS, not significant; OR, odds ratio; PPV, positive predictive value; PSV, peak systolic velocities; PTA, percutaneous transluminal angioplasty; PTFE, polytetrafluoroethylene; pt, patient; PSV; u/s, ultrasound; ROC, receiver operating characteristic; and Vr, velocity ratio.
