PREAMBLE
Since 1980, the American College of Cardiology (ACC) and American Heart Association (AHA) have translated scientific evidence into clinical practice guidelines (guidelines) with recommendations to improve cardiovascular health. These guidelines, which are based on systematic methods to evaluate and classify evidence, provide a cornerstone for quality cardiovascular care. The ACC and AHA sponsor the development and publication of guidelines without commercial support, and members of each organization volunteer their time to the writing and review efforts. Guidelines are official policy of the ACC and AHA.

Intended Use
Practice guidelines provide recommendations applicable to patients with or at risk of developing cardiovascular disease. The focus is on medical practice in the United States, but guidelines developed in collaboration with other organizations may have a global impact. Although guidelines may be used to inform regulatory or payer decisions, their intent is to improve patients’ quality of care and align with patients’ interests. Guidelines are intended to define practices meeting the needs of patients in most, but not all, circumstances and should not replace clinical judgment.

Clinical Implementation
Guideline recommended management is effective only when followed by healthcare providers and patients. Adherence to recommendations can be enhanced by shared decision making between healthcare providers and patients, with patient engagement in selecting interventions based on individual values, preferences, and associated conditions and comorbidities.

METHODOLOGY AND MODERNIZATION
The ACC/AHA Task Force on Clinical Practice Guidelines (Task Force) continuously reviews, updates, and modifies guideline methodology on the basis of published standards from organizations including the Institute of Medicine1,2 and on the basis of internal reevaluation. Similarly, the presentation and delivery of guidelines are reevaluated and modified on the basis of evolving technologies and other factors to facilitate optimal dissemination of information at the point of care to healthcare professionals. Given time constraints of busy healthcare providers and the need to limit text, the current guideline format delineates that each recommendation be supported by limited text (ideally, <250 words) and hyperlinks to supportive evidence summary tables. Ongoing efforts to further limit text are underway. Recognizing the importance of cost–value considerations in certain guidelines, when appropriate and feasible, an analysis of the value of a drug, device, or intervention may be performed in accordance with the ACC/AHA methodology.3

To ensure that guideline recommendations remain current, new data are reviewed on an ongoing basis, with full guideline revisions commissioned in approximately 6-year cycles. Publication of new, potentially practice-changing study results that are relevant to an existing or new drug, device, or management strategy will prompt evaluation by the Task Force, in consultation with the relevant guideline writing committee, to determine whether a focused
update should be commissioned. For additional information and policies regarding guideline development, we encourage readers to consult the ACC/AHA guideline methodology manual and other methodology articles.

Selection of Writing Committee Members

The Task Force strives to avoid bias by selecting experts from a broad array of backgrounds. Writing committee members represent different geographic regions, sexes, ethnicities, races, intellectual perspectives/biases, and scopes of clinical practice. The Task Force may also invite organizations and professional societies with related interests and expertise to participate as partners, collaborators, or endorsers.

Relationships With Industry and Other Entities

The ACC and AHA have rigorous policies and methods to ensure that guidelines are developed without bias or improper influence. The complete relationships with industry and other entities (R1-W1) policy can be found online. Appendix 1 of the current document lists writing committee members’ relevant RWI. For the purposes of full transparency, writing committee members’ comprehensive disclosure information is available online, as is comprehensive disclosure information for the Task Force.

Evidence Review and Evidence Review Committees

When developing recommendations, the writing committee uses evidence-based methodologies that are based on available data. Literature searches focus on randomized controlled trials (RCTs) but also include registries, nonrandomized comparative and descriptive studies, case series, cohort studies, systematic reviews, and expert opinion. Only key references are cited.

An independent evidence review committee (ERC) is commissioned when there are 1 or more questions deemed of utmost clinical importance that merit formal systematic review. This systematic review will strive to determine which patients are most likely to benefit from a drug, device, or treatment strategy and to what degree. Criteria for commissioning an ERC and formal systematic review include: a) the absence of a current authoritative systematic review, b) the feasibility of defining the benefit and risk in a time frame consistent with the writing of a guideline, c) the relevance to a substantial number of patients, and d) the likelihood that the findings can be translated into actionable recommendations. ERC members may include methodologists, epidemiologists, healthcare providers, and biostatisticians.

When a formal systematic review has been commissioned, the recommendations developed by the writing committee on the basis of the systematic review are marked with “n.”

Guideline-Directed Management and Therapy

The term guideline-directed management and therapy (GDMT) encompasses clinical evaluation, diagnostic testing, and pharmacological and procedural treatments. For these and all recommended drug treatment regimens, the reader should confirm the dosage by reviewing product insert material and evaluate the treatment regimen for contraindications and interactions. Recommendations are limited to drugs, devices, and treatments approved for clinical use in the United States.

Class of Recommendation and Level of Evidence

The Class of Recommendation (COR) indicates the strength of the recommendation, encompassing the estimated magnitude and certainty of benefit in proportion to risk. The Level of Evidence (LOE) rates the quality of scientific evidence that supports the intervention on the basis of the type, quantity, and consistency of data from clinical trials and other sources (Table 1).

Glenn N. Levine, MD, FACC, FAHA
Chair, ACC/AHA Task Force on Clinical Practice Guidelines

1. INTRODUCTION

The focus of the “2014 AHA/ACC Guideline for the Management of Patients With Valvular Heart Disease” was the diagnosis and management of adult patients with valvular heart disease (VHD). The field of VHD is rapidly progressing, with new knowledge of the natural history of patients with valve disease, advances in diagnostic imaging, and improvements in catheter-based and surgical interventions. Several randomized controlled trials (RCTs) have been published since the 2014 VHD guideline, particularly with regard to the outcomes of interventions. Major areas of change include indications for transcatheter aortic valve replacement (TAVR), surgical management of the patient with primary and secondary mitral regurgitation (MR), and management of patients with valve prostheses.

All recommendations (new, modified, and unchanged) for each clinical section are included to provide a comprehensive assessment. The text explains new and modified recommendations, whereas recommendations from the previous guideline that have been deleted or superseded no longer appear. Please consult the full-text version of the 2014 VHD guideline for text and evidence tables supporting the unchanged recommendations and for clinical areas not addressed in this focused update. Individual recommendations in this focused update will be incorporated into the full-text guideline in the future. Recommendations from the prior guideline that remain current have been included for completeness but the LOE reflects the COR/LOE system used when initially developed. New and modified recommendations in this focused update reflect the latest COR/LOE system, in which LOE B and C are subcategorized for greater specificity. The section numbers correspond to the full-text guideline sections.

</table>

COR and LOE are determined independently (any COR may be paired with any LOE). A recommendation with LOE C does not imply that the recommendation is weak. Many important clinical questions addressed in guidelines do not lend themselves to clinical trials. Although RCTs are unavailable, there may be a very clear clinical consensus that a particular test or therapy is useful or effective.

* The outcome or result of the intervention should be specified (an improved clinical outcome or increased diagnostic accuracy or incremental prognostic information).

† For comparative-effectiveness recommendations (COR I and IIa; LOE A and B only), studies that support the use of comparator verbs should involve direct comparisons of the treatments or strategies being evaluated.

‡ The method of assessing quality is evolving, including the application of standardized, widely used, and preferably validated evidence grading tools; and for systematic reviews, the incorporation of an Evidence Review Committee.

COR indicates Class of Recommendation; EO, expert opinion; LD, limited data; LOE, Level of Evidence; NR, nonrandomized; R, randomized; and RCT, randomized controlled trial.

1.1. Methodology and Evidence Review

To identify key data that might influence guideline recommendations, the Task Force and members of the 2014 VHD guideline writing committee reviewed clinical trials that were presented at the annual scientific meetings of the ACC, AHA, European Society of Cardiology, and other groups and that were published in peer-reviewed format from October 2013 through November 2016. The evidence is summarized in tables in the Online Data Supplement.

1.2. Organization of the Writing Group

For this focused update, representative members of the 2014 VHD writing committee were invited to participate, and they were joined by additional invited members to form a new writing group, referred to as the 2017 focused update writing group. Members were required to disclose all RWI relevant to the data under consideration. The group was composed of experts representing cardiovascular medicine, cardiovascular imaging,
interventional cardiology, electrophysiology, cardiac surgery, and cardiac anesthesiology. The writing group included representatives from the ACC, AHA, American Association for Thoracic Surgery (AATS), American Society of Echocardiography (ASE), Society for Cardiovascular Angiography and Interventions (SCAI), Society of Cardiovascular Anesthesiologists (SCA), and Society of Thoracic Surgeons (STS).

1.3. Document Review and Approval

The focused update was reviewed by 2 official reviewers each nominated by the ACC and AHA; 1 reviewer each from the AATS, ASE, SCAI, SCA, and STS; and 40 content reviewers. Reviewers’ RWI information is published in this document (Appendix 2).

This document was approved for publication by the governing bodies of the ACC and the AHA and was endorsed by the AATS, ASE, SCAI, SCA, and STS.

2. GENERAL PRINCIPLES

2.4. Basic Principles of Medical Therapy

2.4.2. Infective Endocarditis Prophylaxis: Recommendation

With the absence of RCTs that demonstrated the efficacy of antibiotic prophylaxis to prevent infective endocarditis (IE), the practice of antibiotic prophylaxis has been questioned by national and international medical societies. Moreover, there is not universal agreement on which patient populations are at higher risk of developing IE than the general population. Protection from endocarditis in patients undergoing high-risk procedures is not guaranteed. A prospective study demonstrated that prophylaxis given to patients for what is typically considered a high-risk dental procedure reduced but did not eliminate the incidence of bacteremia. A 2013 Cochrane Database systematic review of antibiotic prophylaxis of IE in dentistry concluded that there is no evidence to determine whether antibiotic prophylaxis is effective or ineffective, highlighting the need for further study of this longstanding clinical dilemma.

The risk of developing IE is higher in patients with underlying VHD. However, even in patients at high risk of IE, evidence for the efficacy of antibiotic prophylaxis is lacking. The lack of supporting evidence, along with the risk of anaphylaxis and increasing bacterial resistance to antimicrobials, led to a revision in the 2007 AHA recommendations for prophylaxis limited to those patients at highest risk of adverse outcomes with IE. These included patients with a history of prosthetic valve replacement, patients with prior IE, select patients with congenital heart disease, and cardiac transplant recipients. IE has been reported to occur after TAVR at rates equal to or exceeding those associated with surgical aortic valve replacement (AVR) and is associated with a high 1-year mortality rate of 75%. IE may also occur after valve repair in which prosthetic material is used, usually necessitating urgent operation, which is not guaranteed. A prospective study demonstrated that prophylaxis given to patients for what is typically considered a high-risk dental procedure reduced but did not eliminate the incidence of bacteremia. A 2013 Cochrane Database systematic review of antibiotic prophylaxis of IE in dentistry concluded that there is no evidence to determine whether antibiotic prophylaxis is effective or ineffective, highlighting the need for further study of this longstanding clinical dilemma.

The consensus of the writing group is that antibiotic prophylaxis is reasonable for the subset of patients at increased risk of developing IE and at high risk of experiencing adverse outcomes from IE. There is no evidence for IE prophylaxis in gastrointestinal procedures or genitourinary procedures, absent known active infection.

### Recommendation for IE Prophylaxis

<table>
<thead>
<tr>
<th>COR</th>
<th>LOE</th>
<th>Recommendation</th>
</tr>
</thead>
</table>
| Ila | C-LD | Prophylaxis against IE is reasonable before dental procedures that involve manipulation of gingival tissue, manipulation of the periapical region of teeth, or perforation of the oral mucosa in patients with the following:
1. Prosthetic cardiac valves, including transcatheter-implanted prostheses and homografts.
2. Prosthetic material used for cardiac valve repair, such as annuloplasty rings and chords.
3. Previous IE.
4. Unrepaired cyanotic congenital heart disease or repaired congenital heart disease, with residual shunts or valvular regurgitation at the site of or adjacent to the site of a prosthetic patch or prosthetic device.
5. Cardiac transplant with valve regurgitation due to a structurally abnormal valve. |

**MODIFIED:** LOE updated from B to C-LD. Patients with transcatheter prosthetic valves and patients with prosthetic material used for valve repair, such as annuloplasty rings and chords, were specifically identified as those to whom it is reasonable to give IE prophylaxis. This addition is based on observational studies demonstrating the increased risk of developing IE and high risk of adverse outcomes from IE in these subgroups. Categories were rearranged for clarity to the caregiver.

The risk of developing IE is higher in patients with underlying VHD. However, even in patients at high risk of IE, evidence for the efficacy of antibiotic prophylaxis is lacking. The lack of supporting evidence, along with the risk of anaphylaxis and increasing bacterial resistance to antimicrobials, led to a revision in the 2007 AHA recommendations for prophylaxis limited to those patients at highest risk of adverse outcomes with IE. These included patients with a history of prosthetic valve replacement, patients with prior IE, select patients with congenital heart disease, and cardiac transplant recipients. IE has been reported to occur after TAVR at rates equal to or exceeding those associated with surgical aortic valve replacement (AVR) and is associated with a high 1-year mortality rate of 75%. IE may also occur after valve repair in which prosthetic material is used, usually necessitating urgent operation, which has high in-hospital and 1-year mortality rates. IE appears to be more common in heart transplant recipients than in the general population, according to limited data. The risk of IE is highest in the first 6 months after transplantation because of endothelial disruption, high-intensity immunosuppressive therapy, frequent central venous catheter access, and frequent endomyocardial biopsies. Persons at risk of developing bacterial IE should establish and maintain the best possible oral health to reduce potential sources of bacterial seeding. Optimal oral health is maintained through regular professional dental care and the use of appropriate dental products, such as manual, powered, and ultrasonic toothbrushes; dental floss; and other plaque-removal devices.

A retrospective analysis of administrative claims databases (>20,000 DOAC-treated patients) showed no difference in the incidence of stroke or major bleeding in patients with rheumatic and nonrheumatic MS if treated with DOAC versus warfarin.35 However, the writing group continues to recommend the use of VKA for patients with rheumatic MS until further evidence emerges on the efficacy of DOAC in this population. (See Section 6.2.2 on Medical Management of Mitral Stenosis in the 2014 guideline.)

I    | C-LD| Anticoagulation is indicated in patients with AF and a CHA2DS2-VASC score of 2 or greater with native aortic valve disease, tricuspid valve disease, or MR.36–38 | NEW: Post hoc subgroup analyses of large RCTs comparing DOAC versus warfarin in patients with AF have analyzed patients with native valve disease other than MS and patients who have undergone cardiac surgery. These analyses consistently demonstrated that the risk of stroke is similar to or higher than that of patients without VHD. Thus, the indication for anticoagulation in these patients should follow GDMT according to the CHA2DS2-VASC score.35–38 |

Many patients with VHD have AF; yet these patients were not included in the original studies evaluating the risk of stroke or in the development of the risk schema such as CHADS2 or CHA2DS2-VASC.39,40 Post hoc subgroup analyses of large RCTs comparing apixaban, rivaroxaban, and dabigatran (DOACs) versus warfarin included patients with VHD, and some included those with bioprosthetic valves or those undergoing valvuloplasty. Although the criteria for nonvalvular AF differed for each trial, patients with significant MS and valve disease requiring an intervention were excluded. There is no clear evidence that the presence of native VHD other than rheumatic MS need be considered in the decision to anticoagulate a patient with AF. On the basis of these findings, the writing group supports the use of anticoagulation in patients with VHD and AF when their CHA2DS2-VASC score is 2 or greater. Patients with a bioprosthetic valve or mitral repair and AF are at higher risk for embolic events and should undergo anticoagulation irrespective of the CHA2DS2-VASC score.

Iia   | C-LD| It is reasonable to use a DOAC as an alternative to a VKA in patients with AF and native aortic valve disease, tricuspid valve disease, or MR and a CHA2DS2-VASC score of 2 or greater.35–38 | NEW: Several thousand patients with native VHD (exclusive of more than mild rheumatic MS) have been evaluated in RCTs comparing DOACs versus warfarin. Subgroup analyses have demonstrated that DOACs, when compared with warfarin, appear as effective and safe in patients with VHD as in those without VHD. |

DOACs appear to be as effective and safe in patients with VHD as they are in those without VHD. In the ROCKET-AF (Rivaroxaban Once Daily Oral Direct Factor Xa Inhibition Compared With Vitamin K Antagonist for Prevention of Stroke and Embolism Trial in Atrial Fibrillation), ARISTOTLE (Apixaban for Reduction in Stroke and Other Thromboembolic Events in Atrial Fibrillation), and RE-LY (Randomized Evaluation of Long-Term Anticoagulant Therapy) trials, 4808, and 3950 patients, respectively, had significant VHD.36–38 This included MR, mild MS, aortic regurgitation, aortic stenosis (AS), and tricuspid regurgitation. These trials consistently demonstrated at least equivalence to warfarin in reducing stroke and systemic embolism. Retrospective analyses of administrative claims databases (>20,000 DOAC-treated patients) correlate with these findings.35 In addition, the rate of intracranial hemorrhage in each trial was lower among patients randomized to dabigatran, rivaroxaban, or apixaban than among those randomized to warfarin, regardless of the presence of VHD.36–38 There is an increased risk of bleeding in patients with VHD versus those without VHD, irrespective of the choice of the anticoagulant.

3. AORTIC STENOSIS

3.2. Aortic Stenosis

3.2.4. Choice of Intervention: Recommendations

The recommendations for choice of intervention for AS apply to both surgical AVR and TAVR; indications for AVR are discussed in Section 3.2.3 in the 2014 VHD guideline. The integrative approach to assessing risk of surgical AVR or TAVR is discussed in Section 2.5 in the 2014 VHD guideline. The choice of proceeding with surgical AVR versus TAVR is based on multiple factors, including the surgical risk, patient frailty, comorbid conditions, and patient preferences and values.41 Concomitant severe coronary artery disease may also affect the optimal intervention because severe multivessel coronary disease may best be served by surgical AVR and coronary artery bypass graft surgery (CABG). See Figure 1 for an algorithm on choice of TAVR versus surgical AVR.
AVR is indicated for survival benefit, improvement in symptoms, and improvement in left ventricular (LV) systolic function in patients with severe symptomatic AS (Section 3.2.3 in the 2014 VHD guideline). 42–48 Given the magnitude of the difference in outcomes between those undergoing AVR and those who refuse AVR in historical series, an RCT of AVR versus medical therapy would not be appropriate in patients with a low-to-intermediate surgical risk (Section 2.5 in the 2014 VHD guideline). Outcomes after surgical AVR are excellent in patients who do not have a high procedural risk. 43–46,48 Surgical series demonstrate improved symptoms after AVR, and most patients have an improvement in exercise tolerance, as documented in studies with pre- and post-AVR exercise stress testing. 43–46,48 The choice of prosthetic valve type is discussed in Section 11.1 of this focused update.

TAVR has been studied in RCTs, as well as in numerous observational studies and multicenter registries that include large numbers of high-risk patients with severe symptomatic AS. 49,50,52–56 In the PARTNER (Placement of Aortic Transcatheter Valve) IA trial of a balloon-expandable valve, 50,53 TAVR (n=348) was noninferior to surgical AVR (n=351) for all-cause death at 30 days, 1 year, 2 years, and 5 years (P=0.001). 53,54 The risk of death at 5 years was 67.8% in the TAVR group, compared with 62.4% in the surgical AVR group (hazard ratio [HR]: 1.04, 95% confidence interval [CI]: 0.86 to 1.24; P=0.76). 52 TAVR was performed by the transfemoral approach in 244 patients and the transapical approach in 104 patients. There was no structural valve deterioration requiring repeat AVR in either the TAVR or surgical AVR groups.

In a prospective study that randomized 795 patients to either self-expanding TAVR or surgical AVR, TAVR was associated with an intention-to-treat 1-year survival rate of 14.2%, versus 19.1% with surgical AVR, equivalent to an absolute risk reduction of 4.9%. 49 The rate of death or stroke at 3 years was lower with TAVR than with surgical AVR (37.3% versus 46.7%; P=0.006). 51 The patient’s values and preferences, comorbidities, vascular access, anticipated functional outcome, and length of survival after AVR should be considered in the selection of surgical AVR or TAVR for those at high surgical risk. The specific choice of a balloon-expandable valve or self-expanding valve depends on patient anatomy and other considerations. 57 TAVR has not been evaluated for asymptomatic patients with severe AS who have a high surgical risk. In these patients, frequent clinical monitoring for symptom onset is appropriate, as discussed in Section 2.3.3 in the 2014 VHD guideline.

TAVR was compared with standard therapy in a prospective RCT of patients with severe symptomatic AS who were deemed inoperable. 53,58,60 The rate of all-cause death at 2 years was lower with TAVR (43.3%) (HR: 0.58; 95% CI: 0.36 to 0.92; P=0.02) than with standard medical therapy (68%). 53,58,60 Standard therapy included percutaneous aortic balloon dilation in 84%. There was a reduction in repeat hospitalization with TAVR (55% versus 72.5%; P<0.001). In addition, only 25.2% of survivors were in New York Heart Association (NYHA) class III or IV 1 year after TAVR, compared with 58% of patients receiving standard therapy (P<0.001). However, the rate of major stroke was higher with TAVR than with standard therapy at 30 days (6.05% versus 1.0%; P=0.06) and remained higher at 2 years (13.8% versus 5.5%; P=0.01). Major vascular complications occurred in 16.2% with TAVR versus 11.1% with standard therapy (P<0.001). 53,58,60
Similarly, in a nonrandomized study of 489 patients with severe symptomatic AS and extreme surgical risk treated with a self-expanding TAVR valve, the rate of all-cause death at 12 months was 26% with TAVR, compared with an expected mortality rate of 43% if patients had been treated medically.59

Thus, in patients with severe symptomatic AS who are unable to undergo surgical AVR because of a prohibitive surgical risk and who have an expected survival of  >1 year after intervention, TAVR is recommended to improve survival and reduce symptoms. This decision should be made only after discussion with the patient about the expected benefits and possible complications of TAVR. Patients with severe AS are considered to have a prohibitive surgical risk if they have a predicted risk with surgery of death or major morbidity (all causes) >50% at 30 days; disease affecting ≥3 major organ systems that is not likely to improve postoperatively; or anatomic factors that preclude or increase the risk of cardiac surgery, such as a heavily calcified (eg, porcelain) aorta, prior radiation, or an arterial bypass graft adherent to the chest wall.58–61

In the PARTNER II (Placement of Aortic Transcatheter Valve II) RCT,62 which enrolled symptomatic patients with severe AS at intermediate risk (STS score ≥4%), there was no difference between TAVR and surgical AVR for the primary endpoint of all-cause death or disabling stroke at 2 years (HR: 0.89; 95% CI: 0.73 to 1.09; P=0.25). All-cause death occurred in 16.7% of those randomized to TAVR, compared with 18.0% of those treated with surgical AVR. Disabling stroke occurred in 6.2% of patients treated with TAVR and 6.3% of patients treated with surgical AVR.62

In an observational study of the SAPIEN 3 valve,63 TAVR was performed in 1077 intermediate-risk patients with severe symptomatic AS, with the transfemoral approach used in 88% of patients. At 1 year, the rate of all-cause death was 7.4%, disabling stroke occurred in 2%, reintervention was required in 1%, and moderate or severe paravalvular aortic regurgitation was seen in 2%. In a propensity score–matched comparison of SAPIEN 3 TAVR patients and PARTNER 2A surgical AVR patients, TAVR was both noninferior and superior to surgical AVR (propensity score pooled weighted proportion difference: −9.2%; 95% CI: −13.0 to −5.4; P<0.0001).63,66

When the choice of surgical AVR or TAVR is being made in an individual patient at intermediate surgical risk, other factors, such as vascular access, comorbid cardiac and noncardiac conditions that affect risk of either approach, expected functional status and survival after AVR, and patient values and preferences, must be considered. The choice of mechanical or bioprosthetic surgical AVR (Section 11 of this focused update) versus a TAVR is an important consideration and is influenced by durability considerations, because durability of transcatheter valves beyond 3 and 4 years is not yet known.65 TAVR has not been studied in patients with severe asymptomatic AS who have an intermediate or low surgical risk. In these patients, frequent clinical monitoring for symptom onset is appropriate, as discussed in Section 2.3.3 in the 2014 VHD guideline. The specific choice of a balloon-expandable valve or self-expanding valve depends on patient anatomy and other considerations.41,57

*Several valve hemodynamic criteria are provided for assessment of MR severity, but not all criteria for each category will be present in each patient. Categorization of MR severity as mild, moderate, or severe depends on data quality and integration of these parameters in conjunction with other clinical evidence.

†The measurement of the proximal isovelocity surface area by 2D TTE in patients with secondary MR underestimates the true ERO because of the crescentic shape of the proximal convergence.

2D indicates 2-dimensional; ERO, effective regurgitant orifice; HF, heart failure; LA, left atrium; LV, left ventricular; MR, mitral regurgitation; and TTE, transthoracic echocardiogram.

7. MITRAL REGURGITATION

7.2. Stages of Chronic MR

In chronic secondary MR, the mitral valve leaflets and chords usually are normal (Table 2 in this focused update; Table 16 from the 2014 VHD guideline). Instead, MR is associated with severe LV dysfunction due to coronary artery disease (ischemic chronic secondary MR) or idiopathic myocardial disease (nonischemic chronic secondary MR). The abnormal and dilated left ventricle causes papillary muscle displacement, which in turn results in leaflet tethering with associated annular dilation that prevents adequate leaflet coaptation. There are instances in which both primary and secondary MR are present. The best therapy for chronic secondary MR is not clear because MR is only 1 component of the disease, with clinical outcomes also related to severe LV systolic dysfunction, coronary disease, idiopathic myocardial disease, or other diseases affecting the heart muscle. Thus, restoration of mitral valve competence is not curative. The optimal criteria for defining severe secondary MR have been controversial. In patients with secondary MR, some data suggest that, compared with primary MR, adverse outcomes are associated with a smaller calculated effective regurgitant orifice, possibly because of the fact that a smaller regurgitant volume may still represent a large regurgitant fraction in the presence of compromised LV systolic function (and low total stroke volume) added to the effects of elevated filling pressures. In addition, severity of secondary MR may increase over time because of the associated progressive LV systolic dysfunction and dysfunction due to adverse remodeling of the left ventricle. Finally, Doppler methods for calculations of effective regurgitant orifice area by the flow convergence method may under-
estimate severity because of the crescentic shape of the regurgitant orifice, and multiple parameters must be used to determine the severity of MR. Even so, on the basis of the criteria used for determination of “severe” MR in RCTs of surgical intervention for secondary MR, the recommended definition of severe secondary MR is now the same as for primary MR (effective regurgitant orifice ≥0.4 cm² and regurgitant volume ≥60 mL), with the understanding that effective regurgitant orifice cutoff of >0.2 cm² is more sensitive and >0.4 cm² is more specific for severe MR. However, it is important to integrate the clinical and echocardiographic findings together to prevent unnecessary operation when the MR may not be as severe as documented on noninvasive studies.

There is concern that the presence of MR leads to progressively more severe MR (“mitral regurgitation begets mitral regurgitation”). The concept is that the initial level of MR causes LV dilatation, which increases stress on the mitral apparatus, causing further damage to the valve apparatus, more severe MR and further LV dilatation, thus initiating a perpetual cycle of ever-increasing LV volumes and MR. Longstanding volume overload leads to irreversible LV dysfunction and a poorer prognosis. Patients with severe MR who develop an EF ≤60% or LVESD ≥40 have already developed LV systolic dysfunction. One study has suggested that for LV function and size to return to normal after mitral valve repair, the left ventricular ejection fraction (LVEF) should be >64% and LVESD <37 mm. Thus, when longitudinal follow-up demonstrates a progressive decrease of EF toward 60% or a progressive increase in LVESD approaching 40 mm, it is reasonable to consider intervention. Nonetheless, the asymptomatic patient with stable LV dimensions and excellent exercise capacity can be safely observed.
Concomitant mitral valve repair is reasonable in patients with chronic moderate primary MR (stage B) when undergoing cardiac surgery for other indications. 2014 recommendation remains current.

Mitral valve surgery may be considered in symptomatic patients with chronic severe primary MR and LVEF less than or equal to 30% (stage D). 2014 recommendation remains current.

Transcatheter mitral valve repair may be considered for severely symptomatic patients (NYHA class III to IV) with chronic severe primary MR (stage D) who have favorable anatomy for the repair procedure and a reasonable life expectancy but who have a prohibitive surgical risk because of severe comorbidities and remain severely symptomatic despite optimal GDMT for heart failure (HF). 2014 recommendation remains current.

MVR should not be performed for the treatment of isolated severe primary MR limited to less than one half of the posterior leaflet unless mitral valve repair has been attempted and was unsuccessful. 2014 recommendation remains current.

Figure 2. Indications for Surgery for MR (Updated Figure 4 From the 2014 VHD guideline).
*MV repair is preferred over MV replacement when possible.
AF indicates atrial fibrillation; CAD, coronary artery disease; CRT, cardiac resynchronization therapy; EF, ejection fraction; ERO, effective regurgitant orifice; HF, heart failure; LV, left ventricular; LVEF, left ventricular ejection fraction; LVESD, left ventricular end-systolic diameter; MR, mitral regurgitation; MV, mitral valve; NYHA, New York Heart Association; PASP, pulmonary artery systolic pressure; RF, regurgitant fraction; RVol, regurgitant volume; and Rx, therapy.
7.4. Chronic Secondary MR

7.4.3. Intervention: Recommendations

Chronic severe secondary MR adds volume overload to a decompensated LV and worsens prognosis. However, there are only sparse data to indicate that correcting MR prolongs life or even improves symptoms over an extended period. Percutaneous mitral valve repair provides a less invasive alternative to surgery but is not approved for clinical use for this indication in the United States.70,72,125–127 The results of RCTs examining the efficacy of percutaneous mitral valve repair in patients with secondary MR are needed to provide information on this patient group.128,129

An RCT showed no clinical benefit of mitral repair in this population of patients, with increased risk of postoperative complications.</td>
<td></td>
</tr>
</tbody>
</table>

In an RCT of mitral valve repair versus MVR in 251 patients with severe ischemic MR, mortality rate at 2 years was 19.0% in the repair group and 23.2% in the replacement group (P=0.39).52 There was no difference between repair and MVR in LV remodeling. The rate of recurrence of moderate or severe MR over 2 years was higher in the repair group than in the replacement group (58.8% versus 3.8%, P<0.001), leading to a higher incidence of HF and repeat hospitalizations in the repair group.52 The high mortality rate at 2 years in both groups emphasizes the poor prognosis of secondary MR. The lack of apparent benefit of valve repair over valve replacement in secondary MR versus primary MR highlights that primary and secondary MR are 2 different diseases.69,125,127,130–139

In an RCT of 301 patients with moderate ischemic MR undergoing CABG, mortality rate at 2 years was 10.6% in the group undergoing CABG alone and 10.0% in the group undergoing CABG plus mitral valve repair (HR in the combined-procedure group=0.90; 95% CI: 0.45 to 1.83; P=0.78).71 There was a higher rate of moderate or severe residual MR in the CABG-alone group (32.3% versus 11.2%; P<0.001), even though LV reverse remodeling was similar in both groups.71 Although rates of hospital readmission and overall serious adverse events were similar in the 2 groups, neurological events and supraventricular arrhythmias were more frequent with combined CABG and mitral valve repair. Thus, only weak evidence to support mitral repair for moderate secondary MR at the time of other cardiac surgery is currently available.71,72

</tbody>
</table>

The choice of valve prosthesis in an individual patient is based on consideration of several factors, including valve durability, expected hemodynamics for a specific valve type and size, surgical or interventional risk, the potential need for long-term anticoagulation, and patient values and preferences. Specifically, the trade-off between the potential need for reintervention for bioprosthetic structural valve deterioration and the risk associated with long-term anticoagulation should be discussed in detail with the patient. Some patients prefer to avoid repeat surgery and are willing to accept the risks and inconvenience of lifelong anticoagulant therapy. Other patients are unwilling to consider long-term VKA therapy because of the inconvenience of monitoring, the attendant dietary and medication interactions, and the need to restrict participation in some types of athletic activity. Several other factors must be taken into consideration in a decision about the type of valve prosthesis, including other comorbidities (Table 3). Age is important because the incidence of structural deterioration of a bioprosthesis is greater in younger patients, but the risk of bleeding from anticoagulation is higher in older patients. A mechanical valve might be a prudent choice for patients for whom a second surgical procedure would be high risk (ie, those with prior radiation therapy or a porcelain aorta). In patients with shortened longevity and/or multiple comorbidities, a bioprosthesis would be most appropriate. In women who desire subsequent pregnancy, the issue of anticoagulation during pregnancy is an additional consideration (Section 13 in the 2014 VHD guideline). The availability of transcatheter valve-in-valve replacement is changing the dynamics of the discussion of the trade-offs between mechanical and bioprosthetic valves, but extensive long-term follow-up of transcatheter valves is not yet available, and not all bioprostheses are suitable for a future valve-in-valve procedure. A valve-in-valve procedure will always require insertion of a valve smaller than the original bioprosthesis, and patient–prosthesis mismatch is a potential problem, depending on the size of the initial prosthesis. Irrespective of whether a mechanical valve or bioprosthesis is placed, a root enlargement should be considered in patients with a small annulus to ensure that there is not an initial patient–prosthesis mismatch.

**Ia** | B-NR | An aortic or mitral mechanical prosthesis is reasonable for patients less than 50 years of age who do not have a contraindication to anticoagulation. | See Online Data (Updated From 2014 VHD Guideline) |

Patients <50 years of age at the time of valve implantation incur a higher and earlier risk of bioprosthetic valve deterioration, Overall, the predicted 15-year risk of needing reoperation because of structural deterioration is 22% for patients 50 years of age, 30% for patients 40 years of age, and 50% for patients 20 years of age, although it is recognized that all bioprostheses are not alike in terms of durability. Anticoagulation with a VKA can be accomplished with acceptable risk in the majority of patients <50 years of age, particularly in compliant patients with appropriate monitoring of International Normalized Ratio (INR) levels. Thus, the balance between valve durability versus risk of bleeding and thromboembolic events favors the choice of a mechanical valve in patients <50 years of age, unless anticoagulation is not desired, cannot be monitored, or is contraindicated. (See the first Class I recommendation for additional discussion).
11.2. Antithrombotic Therapy for Prosthetic Valves

11.2.1. Diagnosis and Follow-Up

Effective oral antithrombotic therapy in patients with mechanical heart valves requires continuous VKA anticoagulation with an INR in the target range. It is preferable to specify a single INR target for each patient and to recognize that the acceptable range includes 0.5 INR units on each side of this target. A specific target is preferable because it reduces the likelihood of patients having INR values consistently near the upper or lower boundary of the range. In addition, fluctuations in INR are associated with an increased incidence of complications in patients with prosthetic heart valves, so patients and caregivers should strive to attain the specific INR value.

<td>B-NR</td>
<td>Anticoagulation with a VKA to achieve an INR of 2.5 is reasonable for at least 3 months and for as long as 6 months after surgical bioprosthetic MVR or AVR in patients at low risk of bleeding.</td>
<td>MODIFIED: LOE updated from C to B-NR. Anticoagulation for all surgical tissue prostheses was combined into 1 recommendation, with extension of the duration of anticoagulation up to 6 months. Stroke risk and mortality rate are lower in patients who receive anticoagulation for up to 6 months after implantation of a tissue prosthesis than in those who do not have anticoagulation. Anticoagulation for a tissue prosthesis is also supported by reports of valve thrombosis for patients undergoing bioprosthetic surgical AVR or MVR, a phenomenon that may be warfarin responsive.</td>
</tr>
</tbody>
</table>

See Online Data Supplement 6.

Many patients who undergo implantation of a surgical bioprosthetic MVR or AVR will not require life-long anticoagulation. However, there is an increased risk of ischemic stroke early after operation, particularly in the first 90 to 180 days after operation with either a bioprosthetic AVR or MVR. Anticoagulation early after valve implantation is intended to decrease the risk of thromboembolism until the prosthetic valve is fully endothelialized. The potential benefit of anticoagulation therapy must be weighed against the risk of bleeding. In a nonrandomized study, patients with a bioprosthetic MVR who received anticoagulation had a lower rate of thromboembolism than those who did not receive therapy with VKA (2.5% per year with anticoagulation versus 3.9% per year without anticoagulation; P=0.05). Even with routine anticoagulation early after valve surgery, the incidence of ischemic stroke within the first 30 postoperative days was higher after replacement with a biological prosthetic (4.6±1.5%) than after mitral valve repair (1.5±0.4%) or replacement with a mechanical prosthetic (1.3±0.8%; P<0.001). Small RCTs have not established a convincing net benefit of anticoagulation after implantation of a bioprosthetic AVR; however, a large observational Danish registry demonstrated a lower risk of stroke and death with VKA extending up to 6 months, without a significantly increased bleeding risk. Concern has also been raised about a higher-than-recognized incidence of bioprosthetic valve thrombosis leaflets after surgical valve replacement. Thus, anticoagulation with an INR target of 2.5 may be reasonable for at least 3 months and perhaps for as long as 6 months after implantation of a surgical bioprosthetic MVR or AVR in patients at low risk of bleeding. Compared with oral anticoagulation alone, the addition of dual-antiplatelet therapy results in at least a 2- to 3-fold increase in bleeding complications, and the recommendations on triple therapy should be followed.
### 11.3. Bridging Therapy for Prosthetic Valves

#### 11.3.1. Diagnosis and Follow-Up

The management of patients with mechanical heart valves for whom interruption of anticoagulation therapy is needed for diagnostic or surgical procedures should take into account the type of procedure; bleeding risk; patient risk factors; and type, location, and number of heart valve prostheses.

#### 11.3.2. Medical Therapy: Recommendations

### Recommendations for Bridging Therapy for Prosthetic Valves

<table>
<thead>
<tr>
<th>COR</th>
<th>LOE</th>
<th>Recommendations</th>
<th>Comment/Rationale</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ia</td>
<td>C-LD</td>
<td>Bridging anticoagulation therapy during the time interval when the INR is subtherapeutic is reasonable on an individualized basis, with the risks of bleeding weighed against the benefits of thromboembolism prevention, for patients who are undergoing invasive or surgical procedures.</td>
<td>MODIFIED: COR updated from I to Ia, LOE updated from C to C-LD. RCTs of bridging anticoagulant therapy versus no bridging therapy for patients with AF who do not have a mechanical heart valve have shown higher risk of bleeding without a change in incidence of thromboembolic events. This may have implications for bridging anticoagulation therapy for patients with prosthetic valves.</td>
</tr>
<tr>
<td>I</td>
<td>C</td>
<td>Continuation of VKA anticoagulation with a therapeutic INR is recommended in patients with mechanical heart valves undergoing minor procedures (such as dental extractions or cataract removal) where bleeding is easily controlled.</td>
<td>2014 recommendation remains current.</td>
</tr>
<tr>
<td>I</td>
<td>C</td>
<td>Temporary interruption of VKA anticoagulation, without bridging agents while the INR is subtherapeutic, is recommended in patients with a bileaflet mechanical AVR and no other risk factors for thrombosis who are undergoing invasive or surgical procedures.</td>
<td>2014 recommendation remains current.</td>
</tr>
<tr>
<td>IIb</td>
<td>B-NR</td>
<td>Anticoagulation with a VKA to achieve an INR of 2.5 may be reasonable for at least 3 months after TAVR in patients at low risk of bleeding.</td>
<td>NEW: Studies have shown that valve thrombosis may develop in patients after TAVR, as assessed by multidetector computerized tomographic scanning. This valve thrombosis occurs in patients who received antiplatelet therapy alone but not in patients who were treated with VKA.</td>
</tr>
<tr>
<td>IIb</td>
<td>B-R</td>
<td>A lower target INR of 1.5 to 2.0 may be reasonable in patients with mechanical On-X AVR and no thromboembolic risk factors.</td>
<td>NEW: A lower target INR was added for patients with a mechanical On-X AVR and no thromboembolic risk factors treated with warfarin and low-dose aspirin. A single RCT of lower-versus standard-intensity anticoagulation in patients undergoing On-X AVR showed equivalent outcomes, but the bleeding rate in the control group was unusually high.</td>
</tr>
</tbody>
</table>

In patients without risk factors who receive a mechanical On-X aortic heart valve (On-X Life Technologies Inc., Austin, Texas), a lower INR target of 1.5 to 2.0 (in conjunction with aspirin 81 mg daily) may be considered for long-term management, beginning 3 months after surgery. Warfarin dosing is targeted to an INR of 2.5 (range 2.0 to 3.0) for the first 3 months after surgery. This is based on a single RCT of lower-versus standard-intensity anticoagulation in patients undergoing On-X AVR, showing equivalent outcomes. The control arm did have a bleeding rate of 3.2% per patient-year. 

Several studies have demonstrated the occurrence of prosthetic valve thrombosis after TAVR, as assessed by multidetector computerized tomography, which shows reduced leaflet motion and hypo-attenuating opacities. The incidence of this finding has varied from 7% to 40%, depending on whether the patients are from a clinical trial or registry and whether some patients received anticoagulation with VKA. Up to 18% of patients with a thrombus formation developed clinically overt obstructive valve thrombosis. A post-TAVR antithrombotic regimen without warfarin seems to predispose patients to the development of valve thrombosis. The utility of the DOACs in this population is unknown at this time.

<th>Comment/Rationale</th>
</tr>
</thead>
<tbody>
<tr>
<td>I</td>
<td>B-NR</td>
<td>Urgent evaluation with multimodality imaging is indicated in patients with suspected mechanical prosthetic valve thrombosis to assess valvular function, leaflet motion, and the presence and extent of thrombus.</td>
<td>MODIFIED: LOE updated to B-NR. Multiple recommendations for imaging in patients with suspected mechanical prosthetic valve thrombosis were combined into a single recommendation. Multimodality imaging with transthoracic echocardiography (TTE), transesophageal echocardiography (TEE), fluoroscopy, and/or computed tomography (CT) scanning may be more effective than one imaging modality alone in detecting and characterizing valve thrombosis. Different imaging modalities are necessary because valve function, leaflet motion, and extent of thrombus should all be evaluated.</td>
</tr>
<tr>
<td>I</td>
<td>B-NR</td>

Obstruction of mechanical prosthetic heart valves may be caused by thrombus formation, pannus ingrowth, or a combination of both. The presentation can vary from mild dyspnea to severe acute pulmonary edema. Urgent diagnosis, evaluation, and therapy are indicated because rapid deterioration can occur if there is thrombus causing dysfunction of leaflet opening. The examination may demonstrate a stenotic murmur and muffled closing clicks, and further diagnostic evaluation is required. TTE and/or TEE should be performed to examine valve function and the status of the left ventricle. Leaflet motion should be visualized with TEE (particularly for a mitral prosthesis) or with CT or fluoroscopy (for an aortic prosthesis). Prolonged periods of observation under fluoroscopy or TEE may be required to diagnose intermittent obstruction. The presence and quantification of thrombus should be evaluated by either TEE or CT. Differentiation of valve dysfunction due to thrombus versus fibrous tissue ingrowth (pannus) is challenging because the clinical presentations are similar. Thrombus is more likely with a history of inadequate anticoagulation, a more acute onset of valve dysfunction, and a shorter time between surgery and symptoms. Mechanical prosthetic valve thrombosis is diagnosed by an abnormally elevated gradient across the prosthesis, with either limited leaflet motion or attached mobile densities consistent with thrombus, or both. Vegetations from E must be excluded. If obstruction is present with normal leaflet motion and no thrombus, either patient–prosthesis mismatch or pannus formation is present (or both). Thrombus formation on the valve in the absence of obstruction can also occur and is associated with an increased risk of embolic events.
11.6.3. Intervention: Recommendation

### Recommendation for Mechanical Prosthetic Valve Thrombosis Intervention

<table>
<thead>
<tr>
<th>COR</th>
<th>LOE</th>
<th>Recommendation</th>
<th>Comment/Rationale</th>
</tr>
</thead>
<tbody>
<tr>
<td>I</td>
<td>B-NR</td>
<td>Urgent initial treatment with either slow-infusion low-dose fibrinolytic therapy or emergency surgery is recommended for patients with a thrombosed leftsided mechanical prosthetic heart valve presenting with symptoms of valve obstruction,224–231</td>
<td>MODIFIED: LOE updated to B-NR. Multiple recommendations based only on NYHA class symptoms were combined into 1 recommendation. Slow-infusion fibrinolytic therapy has higher success rates and lower complication rates than prior high-dose regimens and is effective in patients previously thought to require urgent surgical intervention. The decision for emergency surgery versus fibrinolytic therapy should be based on multiple factors, including the availability of surgical expertise and the clinical experience with both treatments.</td>
</tr>
</tbody>
</table>

Mechanical left-sided prosthetic valve obstruction is a serious complication with high mortality and morbidity and requires urgent therapy with either fibrinolytic therapy or surgical intervention. There has not been an RCT comparing the 2 interventions, and the literature consists of multiple case reports, single-center studies, multicenter studies, registry reports, and meta-analyses—with all the inherent problems of differing definitions of initial diagnosis, fibrinolytic regimens, and surgical expertise224–235 (Data Supplement 7A). The overall 30-day mortality rate with surgery is 10% to 15%, with a lower mortality rate of <5% in patients with NYHA class I/II symptoms,225,226,232–234 The results of fibrinolytic therapy before 2013 showed an overall 30-day mortality rate of 7% and hemodynamic success rate of 75% but a thromboembolism rate of 13% and major bleeding rate of 6% (intracerebral hemorrhage, 3%).234,235 However, recent reports using an echocardiogram-guided slow-infusion low-dose fibrinolytic protocol have shown success rates >90%, with embolic event rates <2% and major bleeding rates <2%.231,235 This fibrinolytic therapy regimen can be successful even in patients with advanced NYHA class and larger-sized thrombi. On the basis of these findings, the writing group recommends urgent initial therapy for prosthetic mechanical valve thrombosis resulting in symptomatic obstruction, but the decision for surgery versus fibrinolysis is dependent on individual patient characteristics that would support the recommendation of one treatment over the other, as shown in Table 4, as well as the experience and capabilities of the institution. All factors must be taken into consideration in a decision about therapy, and the decision-making process shared between the caregiver and patient. Final definitive plans should be based on the initial response to therapy.

### 11.7. Prosthetic Valve Stenosis

Surgical reoperation to replace the stenotic prosthetic heart valve has been the mainstay treatment modality. Although it is associated with acceptable mortality and morbidity in the current era, it remains a serious clinical event and carries a higher risk than the initial surgery. Reoperation is usually required for moderate-to-severe prosthetic dysfunction (structural and nonstructural), dehiscence, and prosthetic valve endocarditis. Reoperation may also be needed for recurrent thromboembolism, severe intravascular hemolysis, severe recurrent bleeding from anticoagulant therapy, and thrombosed prosthetic valves. In 2015, catheter-based therapy with transcatheter valve-in-valve emerged as an acceptable alternative to treat high- and extreme-risk patients with bioprosthetic aortic valve stenosis (stenosis, insufficiency, or combined) in the absence of active IE.154

Symptomatic prosthetic valve stenosis secondary to thrombosis is observed predominantly with mechanical valves. Mechanical prosthetic valve thrombosis and its treatment are discussed in Section 11.6. Bioprosthetic valve thrombosis can result in thromboembolic events or obstruction. In a pooled analysis from 3 studies including 187 patients who underwent either TAVR or bioprosthetic surgical AVR, reduced leaflet motion was noted on 4-dimensional volume-rendered CT imaging in 21% of patients.203 In this small cohort, therapeutic anticoagulation with warfarin was associated with lower incidence of reduced leaflet motion than that associated with dual antiplatelet therapy, as well as more restoration of leaflet motion on follow-up CT imaging. Subclinical leaflet thrombosis was identified as the likely cause on the basis of advanced and characteristic imaging findings.203 As outlined by the US Food and Drug Administration,

CAD indicates coronary artery disease; and NYHA, New York Heart Association.
most cases of reduced leaflet motion (which occurs in 10% to 40% of TAVR patients and 8% to 12% of surgical AVR patients) were discovered by advanced imaging studies in asymptomatic patients. The diagnosis of bioprosthetic valve thrombosis remains difficult, with most suspected bioprosthetic valve thrombosis based on increased transvalvular gradients.

In some patients, the size of the prosthetic valve that can be implanted results in inadequate blood flow to meet the metabolic demands of the patient, even when the prosthetic valve itself is functioning normally. This situation, called patient–prosthesis mismatch (defined as an indexed effective orifice area ≤0.85 cm²/m² for aortic valve prostheses), is a predictor of a high transvalvular gradient, persistent LV hypertrophy, and an increased rate of cardiac events after AVR. The impact of a relatively small valve area is most noticeable with severe patient–prosthesis mismatch, defined as an indexed orifice area <0.65 cm²/m². Patient–prosthesis mismatch is especially detrimental in patients with reduced LVEF and may decrease the likelihood of resolution of symptoms and improvement in LVEF. Patient–prosthesis mismatch can be avoided or reduced by choice of a valve prosthesis that will have an adequate indexed orifice area, determined by the patient’s body size and annular dimension. In some cases, annular enlargement or other approaches may be needed to allow implantation of an appropriately sized valve or avoidance of a prosthetic valve. With bileaflet mechanical valves, patterns of blood flow are complex, and significant pressure recovery may be present; this may result in a high velocity across the prosthesis that should not be mistaken for prosthetic valve stenosis or patient–prosthesis mismatch, particularly in those with small aortic diameters.

<tr>
<td><strong>I</strong> C</td>
<td>Repeat valve replacement is indicated for severe symptomatic prosthetic valve stenosis.239–241</td>
</tr>
</tbody>
</table>

There are no medical therapies known to prevent or treat bioprosthetic valve degeneration. However, bioprosthetic valve thrombosis may present with slowly progressive stenosis months to years after implantation. Small, nonrandomized studies support the use of VKAs to treat patients with bioprosthetic valve thrombosis after both surgical AVR and TAVR. In a retrospective single-center report of 31 patients with bioprosthetic valve thrombosis who were initially treated with either a VKA or surgery/thrombolysis, VKA-treated patients had 87% thrombus resolution and experienced hemodynamic and clinical improvement comparable to surgery/thrombolysis, with no complications. Notably, in that case series, the peak incidence of bioprosthetic valve thrombosis occurred 13 to 24 months after implantation, with the longest interval being 6.5 years. Surgery or thrombolysis may still be needed for patients who are hemodynamically unstable or have advanced and refractory HF, large mobile thrombus, or high risk of embolism. At present, the DOACs have not been adequately studied, nor has the US Food and Drug Administration approved them for prophylaxis or treatment of prosthetic valve thrombosis.

The VIVID (Valve-In-Valve International Data) Registry is the largest registry to date examining outcomes of the transcatheter valve-in-valve procedure in 459 patients, of whom about 40% had isolated stenosis and 30% had combined regurgitation and stenosis. Within 1 month after the valve-in-valve procedure, 7.6% of patients died, 1.7% had a major stroke, and 93% of survivors experienced good functional status (NYHA class I/II). The overall 1-year survival rate was 83.2%. In nonrandomized studies and a systematic review comparing outcomes and safety of the transcatheter valve-in-valve procedure with repeat surgical AVR, the valve-in-valve procedure was found to have similar hemodynamic outcomes, lower stroke risk, and reduced bleeding risk as compared with repeat surgery. No data are available yet on the durability and long-term outcomes after transcatheter valve-in-valve procedures. There are also unique clinical and anatomic challenges, requiring experienced operators with an understanding of the structural and fluoroscopic characteristics of the failed bioprosthetic valve. An anticipated hemodynamic improvement from the transcatheter valve-in-valve procedure occurs only in patients with larger-sized prostheses, because a smaller-sized valve will always be placed within a failing bioprosthesis. In 2015, the US Food and Drug Administration approved the transcatheter heart valve-in-valve procedure for patients with symptomatic heart disease due to stenosis of a surgical bioprosthetic aortic valve who are at high or greater risk for open surgical therapy (as judged by a heart team, including a cardiac surgeon). The transcatheter aortic valve-in-valve procedure is not currently approved to treat para-prosthetic valve regurgitation or for failed/degenerated transcatheter heart valves; and it is contraindicated in patients with IE. Transcatheter valve-in-valve implantation has also been successfully performed for failed surgical bioprostheses in the mitral, pulmonic, and tricuspid positions.
11.8. Prosthetic Valve Regurgitation

11.8.3. Intervention: Recommendations

<table>
<thead>
<tr>
<th>COR</th>
<th>LOE</th>
<th>Recommendations</th>
<th>Comment/Rationale</th>
</tr>
</thead>
<tbody>
<tr>
<td>I</td>
<td>B</td>
<td>Surgery is recommended for operable patients with mechanical heart valves with intractable hemolysis or HF due to severe prosthetic or paraprosthetic regurgitation.250,251</td>
<td>2014 recommendation remains current.</td>
</tr>
</tbody>
</table>

MODIFIED: LOE updated from C to C-LD. A specific indication for surgery is the presence of severe bioprosthetic regurgitation in a patient with acceptable operative risk. With the new recommendation for valve-in-valve therapy, indications for intervention need to account for patients who would benefit from surgery versus those who would benefit from transcatheter therapy, determined by type of valve, symptomatic status, and risk of reoperation.

See Online Data Supplement 23 (Updated From 2014 VHD Guideline)

Bioprosthetic valve degeneration can result in regurgitation due to leaflet calcification and noncoaptation or leaflet degeneration with a tear or perforation. Even in asymptomatic patients with severe bioprosthetic regurgitation, valve replacement is reasonable because of the risk of sudden clinical deterioration if further leaflet tearing occurs.241 The increased risk of a repeat operation must always be taken into consideration. The type of valve prosthesis and method of replacement selected for a patient undergoing reoperation depend on the same factors as those for patients undergoing a first valve replacement.

| IIa | B   | Percutaneous repair of paravalvular regurgitation is reasonable in patients with prosthetic heart valves and intractable hemolysis or NYHA class III/IV HF who are at high risk for surgery and have anatomic features suitable for catheter-based therapy when performed in centers with expertise in the procedure.252-254 | 2014 recommendation remains current. |

NEW: Registries and case series of patients have reported on the short-term outcomes and complication rates for patients with bioprosthetic aortic regurgitation who have undergone transcather valve-in-valve replacement.

See Online Data Supplement 9.

The VIVID (Valve-In-Valve International Data) Registry is the largest registry to date examining outcomes of the transcather valve-in-valve procedure in 459 patients, of whom 30% had severe prosthetic valve regurgitation and 30% had combined regurgitation and stenosis.154 Within 1 month after the valve-in-valve procedure, 7.6% of patients died, 1.7% had a major stroke, and 93% of survivors experienced good functional status (NYHA class I/II). The overall 1-year survival rate was 83.2%.154 In nonrandomized studies and a systematic review comparing outcomes and safety of the transcather valve-in-valve procedure with repeat surgical AVR, the valve-in-valve procedure was found to have similar hemodynamic outcomes, lower stroke risk, and reduced bleeding risk as compared with repeat surgery.248 No data are available yet on the durability and long-term outcomes after transcather valve-in-valve procedures. There are also unique clinical and anatomic challenges requiring experienced operators with an understanding of the structural and fluoroscopic characteristics of the failed bioprosthetic valve. The use of transcather valve-in-valve procedures to treat bioprosthetic valve regurgitation should be applied only to patients with larger-sized prostheses for whom hemodynamic improvement is anticipated. The transcather aortic valve-in-valve procedure is not currently approved to treat paraprosthetic valve regurgitation or failed/degenerated transcather heart valves, and it is contraindicated in patients with IE. Transcather valve-in-valve implantation has also been successfully performed for failed surgical bioprostheses in the mitral, pulmonic, and tricuspid positions.

<td>B-NR</td>
<td>Operation without delay may be considered in patients with IE and an indication for surgery who have suffered a stroke but have no evidence of intracranial hemorrhage or extensive neurological damage.284,285</td>
<td>NEW: The risk of postoperative neurological deterioration is low after a cerebral event that has not resulted in extensive neurological damage or intracranial hemorrhage. If surgery is required after a neurological event, recent data favor early surgery for better overall outcomes.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>See Online Data Supplement 24 (Updated From 2014 VHD Guideline)</td>
<td></td>
</tr>
</tbody>
</table>

Stroke is an independent risk factor for postoperative death in IE patients. Recommendations about the timing of operative intervention after a stroke in the setting of IE are hindered by the lack of RCTs and reliance on single-center experiences. In early observational data, there was a significantly decreased risk of in-hospital death when surgery was performed >4 weeks after stroke.284 These data were not risk adjusted. In an observational study that did adjust for factors such as age, paravalvular abscess, and HF, the risk of in-hospital death was not significantly higher in the group who underwent surgery within 4 weeks of hemorrhagic stroke.285

| IIb | B-NR | Delaying valve surgery for at least 4 weeks may be considered for patients with IE and major ischemic stroke or intracranial hemorrhage if the patient is hemodynamically stable.286 | NEW: In patients with extensive neurological damage or intracranial hemorrhage, cardiac surgery carries a high risk of death if performed within 4 weeks of a hemorrhagic stroke. |
|     |      | See Online Data Supplement 24 (Updated From 2014 VHD Guideline)                |                                                                                   |

Patients with hemorrhagic stroke and IE have a prohibitively high surgical risk for at least 4 weeks after the hemorrhagic event. One multicenter observational study286 showed wide variation in patient deaths when those who underwent surgery within 4 weeks of a hemorrhagic stroke were compared with those whose surgery was delayed until after 4 weeks (75% versus 40%, respectively). The percentage of new bleeds postoperatively was 50% in patients whose surgery was performed in the first 2 weeks, 33% in patients whose surgery was performed in the third week, and 20% in patients whose surgery was performed at least 21 days after the neurological event.286

This table represents relationships of committee members with industry and other entities that were determined to be relevant to this document. These relationships were reviewed and updated in conjunction with all meetings and/or conference calls of the writing committee during the document development process. The table does not necessarily reflect relationships with industry at the time of publication. A person is deemed to have a significant interest in a business if the interest represents ownership of ≥5% of the voting stock or share of the business entity, or ownership of ≥$5000 of the fair market value of the business entity; or if funds received by the person from the business entity exceed 5% of the person's gross income for the previous year. Relationships that exist with no financial benefit are also included for the purpose of transparency. Relationships in this table are modest unless otherwise noted. According to the ACC/AHA, a person has a relevant relationship if: a) the relationship or interest relates to the same or similar subject matter, intellectual property or asset, topic, or issue addressed in the document; or b) the company/entity (with whom the relationship exists) makes a drug, drug class, or device addressed in the document; or c) the person or a member of the person's household, has a reasonable potential for financial, professional or other personal gain or loss as a result of the issues/content addressed in the document.

*Writing committee members are required to recuse themselves from voting on sections to which their specific relationships with industry and other entities may apply. Section numbers pertain to those in the full-text guideline.

†No financial benefit.

‡Significant relationship.

ACC indicates American College of Cardiology; AHA, American Heart Association; Partner, Placement of Aortic Transcatheter Valve; Perigon, Pericardial Surgical Aortic Valve Replacement; and VA, Veterans Affairs.

This table represents the relationships of reviewers with industry and other entities that were disclosed at the time of peer review, including those not deemed to be relevant to this document, at the time this document was under review. The table does not necessarily reflect relationships with industry at the time of publication. A person is deemed to have a significant interest in a business if the interest represents ownership of ≥25% of the voting stock or share of the business entity, or ownership of ≥$5000 of the fair market value of the business entity; or if funds received by the person from the business entity exceed 5% of the person’s gross income for the previous year. Relationships that exist with no financial benefit are also included for the purpose of transparency. Relationships in this table are modest unless otherwise noted. Names are listed in alphabetical order within each category of review. Please refer to http://www.acc.org/guidelines/about-guidelines-and-clinical-documents/relationships-with-industry-policy for definitions of disclosure categories or additional information about the ACC/AHA Disclosure Policy for Writing Committees.

*Significant relationship.
†No financial benefit.

AAFP indicates American Academy of Family Physicians; AATS, American Association for Thoracic Surgery; ABIM, American Board of Internal Medicine; ACC, American College of Cardiology; ACP, American College of Physicians; AHA, American Heart Association; ASE, American Society of Echocardiography; CSE, Canadian Society of Echocardiography; DSMB, data safety monitoring board; FH, familial hyperlipidemia; NHLBI, National Heart, Lung, and Blood Institute; NIH, National Institutes of Health; SCAI, Society for Cardiovascular Angiography and Interventions; SCA, Society of Cardiovascular Anesthesiologists; STS, Society of Thoracic Surgeons; UT, University of Texas; and WVU, West Virginia University.

adults with predisposing cardiac conditions, antibiotics prophylaxis eligible

Exclusion criteria: N/A

Results: 
• The results were extrapolated to general French population.
• Risk of developing IE in unprotected procedure:
  • 1 in 10,700 for prosthetic valve predisposing cardiac conditions
  • 1 in 54,300 for native valve predisposing cardiac conditions
• Risk of developing IE in protected procedures:
  • 1 in 150,000

Exclusion criteria:

N/A

Results:

• The results were extrapolated to general French population.

Strøm BL, et al., 1998

Study type: Observational case control

Inclusion criteria: Subjects with community acquired IE discharged within 3 mo and matched community residents

Exclusion criteria: IE due to IV drug abuse, <18 y of age, hospital acquired IE

1° endpoint: N/A

Results:

• Dental treatment not more common in cases compared to controls (adjusted OR: 0.8, 95% CI: 0.4–1.5)
• Cases with Hx of MV prolapse OR: 19.4; congenital heart disease OR: 6.7, valvular surgery OR: 74.6, rheumatic fever OR: 13.4; heart murmur OR: 4.2
• Prophylaxis dental therapy was significantly low (p=0.03) in cases with cardiac lesions as compared to controls

Strom BL, et al., 1998

Study type: Observational case control

Inclusion criteria: Subjects with community acquired IE discharged within 3 mo and matched community residents

Exclusion criteria: IE due to IV drug abuse, <18 y of age, hospital acquired IE

1° endpoint: N/A

Results:

• Dental treatment not more common in cases compared to controls (adjusted OR: 0.8, 95% CI: 0.4–1.5)
• Cases with Hx of MV prolapse OR: 19.4; congenital heart disease OR: 6.7, valvular surgery OR: 74.6, rheumatic fever OR: 13.4; heart murmur OR: 4.2
• Prophylaxis dental therapy was significantly low (p=0.03) in cases with cardiac lesions as compared to controls

Cardiac valvular abnormalities associated with IE more than the dental treatment

| Mouget FK, et al., 2015: (9) 25758845 | Aim: To assess the impact of AP on bacteremia  
Study type: Double-blind, randomized, placebo-controlled  
Size: n=290 pts | Inclusion criteria: 2008 cohort urgent care presentation for tooth extraction.  
Exclusion criteria: <10 teeth antibiotic use within 2 wk. Need for AP based on practice guidelines active viral disease, Immunosuppressed, poorly-controlled systemic disease penicillin allergy, fever, cellulitis, chewing/tooth brushing within 1 h. | Intervention:  
• Tooth brushing (n=98 pts)  
• Single tooth extraction with AP (n=96 pts) | 1° endpoint: Bacteremia  
32% brushing  
33% amoxicillin  
60% placebo | Given frequency of IE causing bacteremia during a tooth brushing; recommend RCT to determine efficacy of prophylaxis for dental procedure; recommend good dental hygiene. |
| Lockhart PB, et al., 2008: (10) 1851739 | Aim: To compare the incidence, duration, type and extent of endocarditis related bacteremia and to determine | Inclusion criteria: Subjects in need for tooth extraction | Intervention:  
• Tooth brushing group (98)  
• Extraction with amoxilllin group (96) | 1° endpoint:  
32/98 bacterial species identified cause IE.  
Cumulative incidence from 6 blood draws | The results cannot be generalized to general public  
Tooth brushing and single tooth-extractions seem to be similar in terms of |
the impact of AP on single tooth extraction.

**Study type:** RCT

**Size:** n=290 pts

Use of systematic antibiotics within previous 2 wk; on AP; active viral disease; immunocompromised; systemic disease with bad prognosis; Hx of penicillin allergy; 100.5°F temp; facial cellulitis; and handling of the gingival tissues within 1 h before the study.

- Extraction with Placebo group (96)
- Amoxicillin resulted in decrease of positive cultures (p<0.05)

**Safety endpoint (if relevant):** N/A

at risk individuals for IE

</table>
### NASPEAF

**Perez-Gomez F, et al., 2004 (13)**

**15489085**

**Aim:** To evaluate the safety and efficacy of combining antiplatelet and moderate intensity anticoagulation therapy in pts with AF.

**Study type:** Multicenter RCT

**Size:** n=1,209 pts, 13 hospitals

**Inclusion criteria:**
- Pts with chronic or documented paroxysmal AF

**Exclusion criteria:**
- Low-risk pts according to SPAF III stratification
- Pts <60 y of age
- Mechanical valve prosthesis,
- Stroke in the previous 6 mo
- Serum creatinine over 3 mg/dl,
- Alcoholism or drug addiction,
- Severe uncontrolled HTN
- Diffuse arteriosclerosis,
- Indication for NSAIDs or indication/contraindication for antiplatelet or anticoagulant therapy

**Intervention:** The high-risk group pts either had anticoagulation (acenocoumarol) with a target INR of 2–3 or the combination therapy with a target INR of 1.4–2.4.

**Comparator:** The intermediate-risk group had 3 arms; oral anticoagulation (acenocoumarol) to a target INR of 2–3; triflusal 600 mg daily, or a combination of both with a target INR of 1.25–2.

**1° endpoint:**
- Composite of vascular death, TIA, and nonfatal stroke or systemic embolism, (whichever event came first)
- 1° outcome was lower in the combined therapy than in the anticoagulant arm in both the intermediate (HR: 0.33; 95% CI: 0.12–0.91; p=0.02) and the high-risk group (HR: 0.51; 95% CI: 0.27–0.96; p=0.03).

**Safety endpoint:** N/A

### RE-LY Sub-analysis

**Ezekowitz, et al 2016 (14)**

**27496855**

**Aim:** Compare pts with and without any valve disease and to compare warfarin or dabigatran.

**Study type:** Post hoc analysis

**Size:** n=3,950 pts with any VHD

**Inclusion criteria:** VHD and AF

**Exclusion criteria:**
- Prosthetic heart valves, significant MS, and VHD requiring intervention

**Intervention:** Warfarin

**Comparator:** Dabigatran

**1° endpoint:**
- The presence of VHD did not influence comparison of dabigatran at either dose with warfarin in terms of stroke or systemic embolism, major bleed, death, or intracranial hemorrhage.

**Safety endpoint:** The baseline characteristics of pts with VHD reflected a higher CV risk than those of pts without VHD
### Data Supplement 4. Nonrandomized Trials, Observational Studies, and/or Registries of Anticoagulation for AF in Patients With VHD (Section 2.4.3)

| Noseworthy PA, et al., 2016 (15) 26896618 | Study type: Retrospective analysis of administrative claims data to compare effectiveness and safety of NOACs with warfarin in pts with AF and VHD | **Inclusion criteria:** Pts with VHD and AF  
**Exclusion criteria:** NA | 1° endpoint: N/A  
Results: N/A | *Combining rheumatic and nonrheumatic MS, NOACs trended toward lower risk of stroke (HR: 0.52 95% CI: 0.15–1.81, p=0.31) and major bleeding (HR: 0.77 95% CI: 0.41–1.43, p=0.40).  
Pts with AS or AR or MR both stroke or systemic embolism and major bleeding were significantly lower in NOACs compared to warfarin* |
| Olesen, et al., 2011 (16) 21282258 | Study type: Nationwide cohort study  
**Size:** n=121,280 pts; 73,538 included in analysis | **Inclusion criteria:** Nonvalvular AF  
**Exclusion criteria:** No previous diagnoses of MV or AV disease, and no MV or AV surgery | 1° endpoint:  
To evaluate the individual risk factors composing the CHADS2 score and the CHA2DS2-VASc score and to calculate the capability of the schemes to predict thromboembolism.  
Results:  
• In pts at low risk, 1.67 per 100 person y (95% CI:1.47–1.89)  
• In pts at intermediate risk, 4.75 per 100 person y (95% CI:4.45–5.07)  
CHA2DS2-VASc performed better than CHADS2 in predicting pts at high risk and low risk | |
| Petty, et al., 2000 (17) 11062286 | Study type: Cohort/epidemiological  
**Size:** n=729 pts | **Inclusion criteria:** Echocardiographic dx of MS (n=19), MR (n=528), AS (n=140), and AR (n=106) between 1985 and 1992  
**Exclusion criteria:** N/A | 1° endpoint:  
Rates and determinants of cerebrovascular events in pts with VHD pts.  
Results: Risk of CVA and death among pts with valve disease was significantly higher than significantly higher than the corresponding age- and sex-adjusted rates for the community  
Independent predictors of CVA were age, AF, and severe AS.  
AS was associated with rates of CVA similar to those for MS and was an independent determinant of CVA events after adjustment for age and AF (RR:3.5) | |

</table>
Suri, et al. 2008 (53) 18922655 Examine early changes in LV size and function after MV repair or replacement Retrospective n=861 pts Mitral repair/replacement N/A Rate of valve repair increased from 78% to 92%. At early echocardiography (mean, 5 d postop), significant decreases in LVEF (mean: 28.8) and LVESD (mean, 27.5). Magnitude of early decline in EF was similar in pts who had MVR and MV replacement.

Quintana, et al. 2014 (54) 26173130 Assess predictors and long-term survival of latent LV dysfunction Retrospective n=1,705 pts Mitral repair Presence vs. absence of early postop LV dysfunction (LVEF <50%) Pts with absence of LV dysfunction had significant and immediate greater enlargement in systolic dimension and decrease in right ventricular systolic pressure. EF recovered to preop levels (>60%) in only one third of pts with postrepair EF<50% vs. two thirds of those with an EF of ≥50% (p<0.001). The overall survival at 5, 10, and 15 y of follow-up was 95%, 85%, and 70.8%, respectively. Postop EF <40% conferred a 70% increase in the hazard of late death: adjusted HR: 1.74 (95% CI: 1.03, 2.92), p=0.037

Suri, et al. 2011 (55) 21257316 To assess the tempo of MR progression, predictors of MR progression, incidence of de novo LV dysfunction, and predictors of LV dysfunction Retrospective observational study n=142 pts N/A - The likelihood of MR progression was higher in those with greater baseline MR grade (mild/mild-moderate 44/124 (31%) vs. moderate/moderate-severe 35/60 (58%) p=0.0008). - LV deterioration occurred even in the absence of MR progression - Multivariable modeling revealed that LVEDD was the only independent predictor OR: 1.15; 95% CI: 1.08, 1.23; p=0.0001 of greater MR progression with time.

McClure 2014
(80) 24521965

1701 pts aged <65 y who underwent AVR between 1992 and 2011. BHV (2nd generation stented), n=769. MHV (bi-leaflet), n=932.
Retrospective Stepwise logistic regression propensity score identified subset of 361 evenly matched pairs.
361 matched pairs (Mean age BHV 53.9 y vs. 53.2 y for MHV).
Concomitant valve, coronary or ventricular procedures. Ross procedure. Homograft or stentless bioprosthetic AVR.
Concomitant root and/or ascending aortic repairs included. Prior cardiac surgery included (1701 of 6794 pts who underwent AVR in this time frame met inclusion criteria) "Isolated" stented bioprosthetic or bi-leaflet mechanical AVR.
Median follow-up for entire cohort 8 y (14484 pt-y) Median follow-up for matched pairs 6.5 y
• For matched cohort:
  30-d mortality: 1.9% BHV vs. 1.4% MHV (p=0.77)
  Survival at 5, 10, 15 and 18 y for BHV vs. MHV: 89% vs. 88%, 78% vs. 79%, 65% vs. 75% and 60% vs 51% (p=0.75).
  Freedom from reoperation at 18 y: 55% BHV vs. 95% MHV (p=0.002)
  Freedom from major bleeding 78% MHV vs. 98% BHV (p=0.002).
  No difference in stroke rates

Du 2014
(81) 25221895
Pts >65 y of age in Medicare data base who underwent AVR between July 1, 2006 and December 31, 2011. MHV, n=19190. BHV, n=47263.
Retrospective analysis. Mixed-effects model adjusting for physician and hospital random effects to estimate ORs of early mortality for MHV vs BHV.
Medicare beneficiaries enrolled in Parts A, B and D for 6 mo before AVR. Age >65 y of age Mean, 77 y of age. 45% of study population underwent concurrent CABG.
Medicare Part C beneficiaries. (limited claims data)
Up to 365 d after surgery
• OR death on d of surgery MHV vs. BHV 1.61 (95% CI: 1.27–2.04; p<0.001); RR: 1.60. NNT: 290.
• OR death within 30 d surgery MHV vs. BHV 1.18 (1.09–1.28), p<0.001. NNT 121.
• No difference between MHV and BHV d 31–365 after surgery
• Consistent findings in subgroup analyses of pts undergoing AVR + CABG but not in subgroup undergoing isolated AVR

Bourguignon 2015A
(82) 25583467
2,659 pts who underwent AVR with the CE-Perimount BHV valve (1984-2008) at a single center
Retrospective, observational
Mean age 70.7±10.4 y of age (range 16–91 y of age) Age <60 y of age: 383 (13%)
Multiple valve replacement
Mean followup 6.7±4.8 y (0–24.6 y)
• Actuarial survival rates 10 y: 52.4% ± 1.2%; 15 y: 31.1% ± 1.4%; 20 y: 14.4% ± 1.7%
• Freedom from reoperation from structural valve deterioration: 60 y or less:15 y:70.8% ± 4.1% 20 y:38.1% ± 5.6%; 60-70 y: 15 y:82.7% ± 2.9% ; 20 y: 59.6% ± 7.6% Over 70 y: >15 y:98.1% ± 0.8%
• Expected valve durability is 19.7 y for the entire cohort.

Isaacs 2015

(87)

25791947

All pts>18 y old who underwent AVR in NIS database.
767,375 implanted valves

Observational

Median age: 74 y for pts receiving BHV
Median age: 67 y for pts receiving MHV.

Pts who underwent a simultaneous valve annuloplasty, valve repair, or mitral or tricuspid valve replacement were excluded.

All pts aged >18 y in the National Inpatient Sample who received an AVR between 1998 and 2011 were studied

• 767,375 implanted valves. 
BHV increased from 37.7% in 1998-2001 to 63.6% in 2007-2011.
• Use of bioprosthetic valves increased across all age groups, most markedly in pts age 55 to 64 y.

| **PROACT** Puskas J 2014 (93) 24512654 | **Aim:** To assess the efficacy and safety of less intensive anticoagulation (INR 1.5–2.0) in high-risk pts receiving an On-X AVR | **Inclusion criteria:** 1. Indication for AVR; age ≥18 y of age 2. One of the following: a. Chronic AF b. EF <0.30 c. LAE (>50 mm) d. LA SEC e. "vascular pathologic features" f. LV or RV aneurysm g. Neurologic events h. Lack of response to ASA or clopidogrel i. Women receiving estrogen 3. Other cardiac surgery allowed: a. CABG b. MV or TV repair c. Ascending aortic replacement d. Maze e. "and so forth" | **Intervention (test group):** Warfarin targeted to INR 1.5-2.0  
**Comparator (control group):** Warfarin targeted to INR 2.0–3.0  
All pts received ASA 81 mg Randomization at 3 mo post-operatively | **1º endpoint:** The 1º endpoints mandated by the FDA included major bleeding events, minor bleeding events, total bleeding events, TIA, hemorrhagic stroke, nonhemorrhagic stroke, any neurologic event, peripheral TE, any TE, valve thrombosis, TE and thrombosis, major event (major bleeding, any TE, valve thrombosis), death (cardiac, noncardiac, valve-related, and all-cause)  
Safety endpoint (if relevant): Incorporated in 1º endpoint above  
Selected Results (test vs. control): 1. Major bleeding rate (%/pt-y) 1.48 vs. 3.31; RR: 0.45; (0.21–0.94, p=0.032) 2. Total bleeding RR: 0.40 (0.24–0.69) p<0.001 3. TE + thrombosis RR: 1.60 (0.82–3.17), p=0.178 3. All events RR: 0.66 (0.44–0.99) p=0.046 | • The 2º endpoints included endocarditis, hemolysis, hemolytic anemia, PVL, structural and nonstructural dysfunction, postoperative NYHA class and echocardiographic Hemodynamics.  
• Comments: TTR 63.8% test group (INR 1.5–2.) vs. 69.8% control group (INR 2.0–3.0)  
• Mean INR 1.89 +/- 0.50 for test group vs. 2.5±0.64 control group (p<0.0001) 14 (3.7%) of pts had AF  
• Unblinded |
| **AREVA** Acar, et al. 1996 (94) 8901659 | **Aim:** To compare moderate oral anticoagulation (INR 2.0–3.0) to higher intensity anticoagulation (INR 3.0–4.5) following single- MV replacement (Omnicarbon or St. Jude) | **Inclusion criteria:** Pts 18–75 y of age, in sinus rhythm, left atrial diameter ≤50 mm  
**Exclusion criteria:** Contraindication to anticoagulant therapy, dialyzed renal failure, hepatic insufficiency, refusal to participate | **Intervention:** INR of 2.0–3.0 (n=188 pts)  
**Comparator:** INR of 3.0–4.5 (n=192 pts) | **1º endpoint:** Thromboembolic, hemorrhagic events, mortality, endocarditis, withdrawal from oral anticoagulant therapy  
Safety endpoint (if relevant): None | • Major and minor bleeding events were significantly lower in the INR 2.0–3.0 group vs. the INR 3.0–4.5 group.  
• NS difference in thromboembolic event rates in the 2.0–3.0 group compared to the 3.0–4.5 group  
• Use of warfarin was similar in both groups  
• Minor complications were similar in both groups  
• NS difference in major complications  
• NS difference in mortality  
• NS difference in endocarditis  
• NS difference in major and minor bleeding events  
• NS difference in atrial fibrillation symptoms  
• NS difference in hospital stay  
• NS difference in length of stay  
• TTR was higher in the 2.0–3.0 group  
•但仍需进一步研究来确定最佳的INR范围。 |

| Brennan et al., 2012 (98) | To evaluate the risks and benefits of short-term anticoagulation in pts receiving an aortic valve bioprosthesis | Pts >65 y who had bioprosthetic AVR surgery performed between 2004–2006 | • Group A: ASA only  
• Group B: ASA and warfarin  
• Group C: Warfarin only | Death, repeat hospitalization for embolic events or bleeding. Among those receiving ASA-only, 3-mo adverse events were low (death, 3.0%; embolic events, 1.0%; bleeding events, 1.0%). Relative to ASA-only, those treated with warfarin plus ASA had a lower adjusted risk of death (RR: 0.80; 95% CI: 0.66–0.96) and embolic event (RR: 0.52; 95% CI: 0.35–0.75) but a higher risk of bleeding (RR: 2.80, 95% CI: 2.18–3.60). Relative to ASA-only, warfarin-only pts had a similar risk of death (RR: 1.01; 95% CI: 0.80–1.27), embolic events (RR: 0.95; 95% CI: 0.61–1.47), and bleeding (RR: 1.23, 95% CI: 0.85–1.79). |
| Egbe AC, et al., 2015 (99) | To determine the diagnostic features of BPVT | 46 of 397 consecutive cases of explanted bioprosthesis in the Mayo Clinic pathology database between 1997–2013 which were diagnosed as BPVT, matched 1:2 for age, sex and bioprosthesis position with pts whose valves were explanted for structural failure | BPVT vs. structural deterioration of bioprosthesis  
Results:  
46 cases of BPVT (11.6%; aortic 29, mitral 9, tricuspid 7, pulmonary 1), mean age 63 y, and 68% were male. 30 (65%) cases occurred >12 mo post-implantation; median bioprosthetic valve longevity was 24 mo (cases) vs. 108 mo (controls) (p<0.001). Independent predictors of BPVT were >50% increase in mean echo-Doppler gradient from baseline within 5 y (OR: 12.7), paroxysmal AF (OR: 5.19), subtherapeutic INR (OR: 7.37), increased cusp thickness (OR: 12.2), and abnormal cusp mobility (OR: 6.94). Presence of all 5 diagnostic features was predictive of BPVT with 76% sensitivity, 93% specificity, 85% positive predictive value, and 89% negative predictive value (p<0.001). |
| Makkar RR, et al., 2015 (100) | To investigate the possibility of subclinical leaflet thrombosis in bioprosthetic AVs after TAVR and the effect of anticoagulation | Pts who had 4D volume rendered CT scans following TAVR implantation in a clinical trial and 2 registry studies | Reduced leaflet motion was noted on CT in 22 of 55 pts (40%) in the clinical trial and 17 of 132 pts (13%) in the 2 registries. Reduced leaflet motion was detected among pts with multiple bioprosthesis types, including transcatheter and surgical bioprostheses. Therapeutic anticoagulation with warfarin, as compared with DAPT, was associated with a decreased incidence of reduced leaflet motion (0% and 55%, respectively, p<0.01 in the clinical trial; and 0% and 29%, respectively, p<0.04 in the pooled registries). In pts reevaluated with follow-up CT, the condition resolved with therapeutic anticoagulation. |

**BPVT** is not uncommon and can occur several years after surgery. A combination of clinical and echocardiographic features can reliably diagnose BPVT.

Hansson NC et al. 2016 (101) 27580689

**Aim:** To assess the incidence, potential predictors, and clinical implications of THV thrombosis as determined by contrast-enhanced MDCT after TAVR

**Study type:** Analysis of contrast enhanced MDCT scans from consecutive pts undergoing TAVR

**Size:** n=405 pts

**Inclusion criteria:** 460 consecutive pts who underwent TAVR at a single center between 2011-2016

**Exclusion criteria:** 55 pts who did not have contrast enhanced MDCT scans at 1-3 mo following TAVR

**Intervention and Comparator:**
- **Group A:** Treatment with warfarin
- **Group B:** No treatment with warfarin

**Results:** MDCT verified THV thrombosis in 28 of 405 (7%) pts. A total of 23 pts had subclinical THV thrombosis, whereas 5 (18%) pts experienced clinically overt obstructive THV thrombosis. The risk of THV thrombosis in pts who did not receive warfarin was higher compared with pts who received warfarin (10.7% vs. 1.8%; RR: 6.09; 95% CI: 1.86–19.84). A larger THV was associated with an increased risk of THV thrombosis (p=0.03). In multivariable analysis, a 29-mm THV (RR: 2.89; 95% CI: 1.44–5.80) and no post-TAVR warfarin treatment (RR: 5.46; 95% CI: 1.68–17.7) independently predicted THV thrombosis. Treatment with warfarin effectively reverted THV thrombosis and normalized THV function in 85% of pts as documented by follow-up TEE and MDCT.

Pache et al. 2016 (102) 26446193

**Aim:** To evaluate the frequency of early hypoattenuated leaflet thickening of transcatheter AVs

**Study type:** Analysis of ECG gated dual source CTA angiography following TAVR at median of 5 d after implantation

**Size:** n=156 pts

**Inclusion criteria:** 249 pts who had TAVR at a single institution between 2014-2015

**Exclusion criteria:** Pts who had a contraindication for CTA due to acute renal failure, impaired renal function, missing consent, or inability to undergo a CTA examination (93 pts)

**Intervention and Comparator:**
- **Group A:** Presence of hypoattenuated leaflet thickening
- **Group B:** Absence of hypoattenuated leaflet thickening

**Results:** Hypo-attenuated leaflet thickening was found in 16 pts [10.3% (95% CI: 5.5%–15.0%)]. Hypo-attenuated leaflet thickening was not associated with clinical symptoms, but a small, albeit significant difference in mean pressure gradient at the time of CTA (11.6 ± 3.4 vs. 14.9 ± 5.3 mm Hg, p=0.026). Full anticoagulation led to almost complete resolution of hypo-attenuated leaflet thickening in 13 pts with follow-up CTA.

- Incidence of THV thrombosis in this large study was 7%.
- A larger THV size may predispose to THV thrombosis, whereas treatment with warfarin appears to have a protective effect.
### Data Supplement 21. *(Updated From 2014 Guideline)* Bridging Anticoagulation Therapy for Mechanical Heart Valves (Section 11.3.2)

27
RCT, double-blind, placebo-controlled trial. Pts with chronic AF or flutter receiving warfarin therapy for at least 3 mo undergoing elective surgery. Mechani+h heart valve, at least 1 CHADS2 risk factor cardiac, intracranial or intraspinal surgery. N=1884; 950 with no bridging therapy. 934 assigned to bridging with low-molecular-weight heparin (100 IU of dalteparin per kilogram of body weight) or matching placebo administered subcutaneously twice daily, from 3 d before the procedure until 24 h before the procedure and then for 5 to 10 d after the procedure. The incidence of arterial thromboembolism was 0.4% in the no-bridging group and 0.3% in the bridging group (risk difference, 0.1 percentage points; 95% CI: −0.6 to 0.8; p=0.01 for noninferiority). The incidence of major bleeding was 1.3% in the no-bridging group and 3.2% in the bridging group (RR: 0.41; 95% CI: 0.20–0.78; p=0.005 for superiority).

Population excluded pts with MHV and was predominantly low risk for thromboembolism.

Randomized, prospective, multicenter, pilot study. Inclusion: Consecutive pts having AVR and/or MV replacement with MHVs for the first time. Exclusion: Need for adjunctive antiplatelet therapy, ASA allergy/intolerance; combined CABG, emergency surgery, follow-up problems, poor compliance, renal or hepatic insufficiency, life expectancy <12 mo. Pts randomized to 2 groups; Group A (n=94): receiving low-intensity VKA treatment (target INR 2.5) [plus ASA (100 mg/d) for the first 6 mo]; Group B (n=104): receiving standard-intensity (moderate to high) VKA treatment (target INR 3.7). 1° outcomes: • Systemic embolism/thromboembolic complications • Major bleeding/bleeding complications • Vascular death Cumulative 1° outcome incidence: GROUP A - 5.8% (95% CI: 0.9–10.7) GROUP B – 4.3% (95% CI: 0.2–8.4), p=0.6. Low-intensity VKA plus ASA for first 6 mo appears as effective and safe as standard-intensity VKA.

### Inclusion Criteria

- **Nagy A et al 2009**
  - Obstructive – restricted leaflet motion with increased gradient, non-obstructive – thrombus on TEE

- **Lengyel M et al 2001**
  - Obstructive – restricted leaflet motion with increased gradient, non-obstructive – thrombus on TEE

- **Karthikeyan G et al 2009**
  - First episode of left sided PVT (immobile or hypomobile leaflets on fluoroscopy)

### Intervention

- **Nagy A et al 2009**
  - Bolus and continuous infusion of SK, UK up to 72 h

- **Lengyel M et al 2001**
  - Accelerated 1.5 °C terminal infusion of SK, UK load with continuous infusion until successful as initial therapy in 30 mitral and 2 aortic obstructive, surgery in 9 mitral and 1 aortic, Nonobstructive-heparin first

- **Karthikeyan G et al 2009**
  - Accelerated 1.5 million units (MU) SK bolus followed by 1 MU/h vs 25 MU bolus followed by 1 MU/h up to 96 h

### Comparator

- **Nagy A et al 2009**
  - N/A

- **Lengyel M et al 2001**
  - N/A

- **Karthikeyan G et al 2009**
  - N/A

### 1st Endpoint

- **Nagy A et al 2009**
  - Complete clinical response = complete hemodynamic response (normalization of gradient with complete leaflet opening on fluoroscopy) in absence of major complication

- **Lengyel M et al 2001**
  - Complete clinical response = complete hemodynamic response (normalization of gradient with complete leaflet opening on fluoroscopy) in absence of major complication

- **Karthikeyan G et al 2009**
  - Complete clinical response = complete hemodynamic response (normalization of gradient with complete leaflet opening on fluoroscopy) in absence of major complication

### Comments

- **Nagy A et al 2009**
  - Size of thrombus unrelated to success or complication rate. NYHA Class III/IV presentation vs III – no difference in success or complication rate of TT. Limitation: single-center study with loss of followup – cannot compare TT mortality vs surgical mortality as 2/3 had surgery after failed TT. Comments: Intention to treat TT mortality 11% and surgical mortality 44% - overall TT mortality 6% and surgical mortality 26%

- **Lengyel M et al 2001**
  - Size of thrombus unrelated to success and complication rate. obstructive and nonobstructive. NYHA Class I/II and 24% om NYHA Class III/IV due to high risk surgery. Heparin ineffective in both obstructive and nonobstructive. Limitation: single-center without a standard process to decide therapy – cannot compare results of high mortality with surgery (29%) to mortality with TT (6%) as sicker pts in the surgery group. Comments: heparin alone inadequate in 82%. Authors state that TT is treatment of choice for all pts with PVT.

- **Karthikeyan G et al 2009**
  - Size of thrombus unrelated to success and complication rate. NYHA Class III/IV presentation vs III – no difference in success or complication rate of TT. Limitation: underpowered to show a difference between the 2 groups. TEE was not performed. Comments: complete clinical response 74 % in NYHA Class III and 24% on NYHA Class II/IV. Only randomized trial thus far with TT therapy, showing a lower success rate than prior studies.
Caceres-Loriga et al 2006

**Aim:** To determine the efficacy and safety of TT for PVT

**Study type:** Single-center retrospective review

**Size:** 69 consecutive pts with PVT

**Inclusion criteria:** Consecutive pts presenting with left sided obstructive PVT and no contraindication to TT

**Exclusion criteria:** 2 pts with a contraindication to TT

**Patient Population:** 78% women, mean age 42 y, NYHA Class III/IV

**Intervention:** bolus and continuous infusion of SK up to 72 h

**Comparator:** N/A

**1° endpoint:** complete hemodynamic response (normalization of gradient with complete leaflet opening on fluoroscopy)

**Results:** complete hemodynamic response 80.6%, partial response 8.3%, no response 11%

**Complications:** 4 deaths, 5 embolic complications (3 CVA and 5 TIA), 3 major hemorrhage (2 intracranial bleeding). 16% had recurrence in follow-up.

**Conclusion:** TT is effective in 80% of pts but with a high rate of embolism. Recurrence rate is high.

**Limitation:** Single-center retrospective study

**Comments:** Authors recommended TT as first line of therapy in all pts

Gupta et al 2000

**Aim:** To determine the short and long-term results of TT for PVT

**Study type:** Single-center retrospective review

**Size:** n=110 consecutive pts with obstructive PVT

**Inclusion criteria:** All pts presenting with left sided obstructive PVT and no contraindication to TT

**Exclusion criteria:** 6 pts with contraindication to thrombolysis

**Patient Population:** 53% women, mean age 68, NYHA Class III/IV

**Intervention:** Bolus and continuous infusion of SK up to 72 h

**Comparator:** N/A

**1° endpoint:** Complete hemodynamic response (normalization of gradient with complete leaflet opening on fluoroscopy)

**Results:** Complete hemodynamic response 81.8%, partial response 10%, and no response 8.2%. 23% had recurrence in follow up.

**Complications:** 8 deaths, 21 embolic complications (6 CVA and 5 TIA), 9 major hemorrhage (5 intracranial bleeding)

**Conclusion:** TT is effective in 80% of pts but with a high rate of embolism, particularly if in AF. Recurrence rate is high.

**Limitation:** Single-center study with 10% lost to follow-up. TEE was not done in majority.

**Comments:** pts who died were primarily those with severe Class IV HF and 3 died within 2 h of infusion (not enough time for TT to work), of incomplete responders only 3/11 did well

Roudaut et al 2009

**Aim:** To define the efficacy and safety of thrombolysis vs surgery for PVT

**Study type:** Single-center retrospective review

**Size:** n=210 pts; treated by TT (n=127 pts) or surgery (n=136 pts)

**Inclusion criteria:** All pts at single institution treated for PVT

**Exclusion criteria:** None

**Patient Population:** 66% women, mean age 59, NYHA Class III/IV

**Intervention:** SK (49), UK (41), rTPA (37), combination (38)

**Comparator:** surgery with either valve replacement (106) or declotting pannus excision (30)

**1° endpoint:** Hemodynamic success (complete normalization of hemodynamics by echo and fluoroscopy)

**Results:** Hemodynamic success higher in surgery 89% vs TT group 71%

**Complications:** Mortality similar (10%) both groups, total complications (25% vs 11%) and embolic events (15% vs 0.7%) higher in TT vs surgery group

**Conclusion:** Surgery had a higher success rate and lower complication rate than TT

**Limitation:** Single-center experience which changed over time – surgery the more preferred therapy with time

**Comments:** NYHA class at presentation was strongest predictor of late death. Long-term follow-up at 6 y– better outcome in terms of mortality and recurrence with surgery 76% of pts were subtherapeutic on their INR before presentation, 23% had temporary cessation of warfarin
Tong AT et al. 2004 (119) 14715187

**Aim:** To determine whether thrombus size can predict outcome of thrombolysis therapy for PVT

**Study type:** Registry of TEE performed prior to TT for PVT

**Size:** n=107 pts entered into registry

**Inclusion criteria:** Pts suspected of PVT obstruction or thrombus formation undergoing TEE prior to TT

**Exclusion criteria:** Patient Population: 107 pts from 14 centers, 71% women, mean age 43, 41% NYHA Class III-IV, valve type (84% mitral, 15 aortic, 4 tricuspid), NYHA Class III-IV 63%, 99 obstructive vs 14 nonobstructive

**Intervention:** Slow infusion SK (54%), UK (17%) or tPA (29%)

**Comparator:** N/A

**1° endpoint:** Complete hemodynamic success (hemodynamics to normal range), partial hemodynamic success (partial improvement in hemodynamics), clinical success (hemodynamic success without complication)

**Results:** Complete hemodynamic success 76%, partial hemodynamic success 8.6%, clinical success 74%

**Complications:** Overall complications in 17.8%. Death 5.6%, left sided embolic rate 14%, major complication of death, CVA, MI, cerebral bleed in 9.3%

**Conclusion:** Thrombus area >0.8cm². HR of stroke and NYHA Class III/IV was predictive of complications and poor outcome

**Limitation:** Registry study from 14 centers with strict inclusion criteria and differing thrombolytic regimens – a study more of the TEE predictors rather than outcome of thrombolysis

**Comments:** Soft mass increased success to 91% but still 75% success without soft mass

Thrombus size was an important predictor of complication even in Class III/IV pts

TROIA Trial. Ozkan M, et al 2013 (120) 23489534

**Aim:** To identify the most effective and safest TEE-guided thrombolytic regimen for PVT.

**Study type:** Single-center, non-randomized, prospective

**Size:** 182 consecutive pts with 220 episodes of PVT

**Inclusion criteria:** Pts with obstructive PVT, nonobstructive PVT with recent thromboembolism, or a thrombus diameter of ≥10 mm

**Exclusion criteria:** Contraindication to TT, nonobstructive PVT with a thrombus diameter of <10 mm and no recent thromboembolism, prosthetic valve obstruction with no thrombus on TEE and normal prosthetic valve leaflet motion

Patient population: 182 pts, 71% female, mean age 43, 41% NYHA Class III/IV, valve type (84% mitral, 10% aortic), 48% obstructive, 52% nonobstructive

**Intervention:** Different thrombolysis regimens:

- Group I: Rapid streptokinase (16)
- Group II: Slow streptokinase (41)
- Group III: High dose IPA (12)
- Group IV: Half dose, bolus and slow tPA infusion (27)
- Group V: Low dose, non-bolus and slow IPA infusion (124)

**Comparator:** N/A

**1° endpoint:** Thrombolytic success

- Obstructive: Decrease gradient, 75% reduction in thrombus size and clinical improvement (complete all 3, partial <3)
- Nonobstructive: >75% reduction thrombus size

**Results:** Successful thrombolysis in 83.2% of cases (68.8%, 85.4%, 75.0%, 81.5%, 85.5% respectively; p=0.46)

**Complications:** Overall complication rate of 18.6%. Lower combined complication rate in Group V (10.5%) vs. other groups (24%-38%)

Absence of mortality in Group V. The predictors of combined mortality plus nonfatal major complications were any TT regimen other than Group V (OR group 1 through IV: 8.2, 3.8, 8.1 and 4.1 respectively, p<0.05 for each)

**Conclusion:** Low-dose nonbolus slow IPA infusion resulted in the highest success rate of thrombolysis and lowest combined complication rate.

**Limitation:** Single-center nonrandomized study with small number of pts in each group, included both obstructive and nonobstructive PVT

**Comments:** 64 pts who had a contraindication to thrombolysis or failed thrombolysis underwent surgery with a 27% mortality

Ozkum M et al, 2013 (121) 23812180

**Aim:** To evaluate the safety and efficacy of low-dose, slow infusion IPA activator for the treatment of PVT in pregnant women

**Inclusion criteria:** Pregnant pts. with obstructive and nonobstructive PVT with recent thromboembolism and thrombus diameter of >5mm and pts with asymptomatic mobile nonobstructive PVT with thrombus

**Intervention:** Low dose IPA – 25 mg over 6 h, repeat at 24 h

**Comparator:** N/A

**1° endpoint:** Thrombolytic success

- Obstructive: Decrease gradient, 75% reduction in thrombus size and clinical improvement (complete all 3, partial <3)
- Nonobstructive: >75% reduction thrombus size

**Result:** 100% thrombolytic success. (Obstructive PVT group thrombus area, mean, 1.7±1.2 cm²; range, 0.8–6

**Conclusion:** Low dose slow infusion of tPA is an effective and safe regimen for PVT in pregnant women

**Limitation:** Single-center nonrandomized trial with small number of pts.; included both obstructive and nonobstructive PVT
| Study type: | Single-center, nonrandomized, prospective (subgroup of TROIA trial) |
| Size: | 24 consecutive pregnant pts with 28 episodes of PVT (all mitral – 23 mechanical) |
| | diameter of ≥10 mm |
| Exclusion criteria: | Pts. with contraindication to TT, asymptomatic non obstructive PVT with a thrombus diameter of <10mm and no recent thromboembolism, pts with imminent abortion or placenta previa, pts with prosthetic valve obstruction with no thrombus on TEE and normal prosthetic valve leaflet motion |
| Patient population: | 24 women during 25 pregnancies and 28 episodes PVT, mean age 29, mean gestational age 19 wk, NYHA class III/IV (50%) obstructive in 15 (all mitral), nonobstructive in 13 |
| | cm²; nonobstructive PVT group, mean, 0.9±0.4 cm²; range, 0.4-1.8 cm²; p=0.022 . No remaining thrombus after TT on TEE |
| Complications: | no complications in the mother, 20 live births with 1 placental hemorrhage and 1 minor bleeding, 20% miscarriages |

**PORMETEE Trial**  
Ozkun M et al 2015  
(122) 26299240

| Aim: | To identify the efficacy and safety of TEE-guided ultraslow infusion of low-dose tPA for PVT. |
| Study type: | Single-center, nonrandomized, prospective |
| Size: | 114 consecutive pts with 120 episodes of PVT (113 mechanical PVT) |
| Inclusion criteria: | Pts with obstructive PVT, nonobstructive PVT with recent thromboembolism, or a thrombus diameter of ≥10 mm |
| Exclusion criteria: | Contraindication to TT, nonobstructive PVT with a thrombus diameter of <10 mm and no recent thromboembolism, Prosthetic valve obstruction with no thrombus on TEE and normal prosthetic valve leaflet motion |
| Patient Population: | 65% female, mean age 49, NYHA Class III/IV (35%), obstructive in 77 (23 aortic, 40 mitral 4 tricuspid, 2 double valve), nonobstructive in 43 (10) |
| Intervention: | Low dose tPA – 25 mg over 6 h, repeat every 24 h |
| Comparator: | N/A |
| 1st endpoint: | Thrombolytic success |
| Obstructive: | Decrease gradient, 75% reduction in thrombus size and clinical improvement (complete all 3, partial <3) |
| Nonobstructive: | >75% reduction thrombus size |
| Result: | Successful thrombolysis in 90%. Only independent predictor of unsuccessful result was higher NYHA Class. |
| Complications: | Total complications in 8 pts (6.7%) – death (0.8%), major complication (3.3%), minor complication (2.5%). – 1 stroke, 1 peripheral embolism and 4 hemorrhage |
| Conclusion: | Low dose nonbolus slow tPA infusion resulted in the high success rate of thrombolysis (90%) and low combined complication rate (embolism 1.7%, major bleed 1.7% minor bleed 1.7%) |
| Limitation: | single-center nonrandomized study with small number of pts, included both obstructive and nonobstructive PVT. Only 4 pts were in NYHA Class IV |
| Comments: | success rate 20% after first dose and required up to 8 doses, Median number sessions >2, median dose tPA = 64 mg |

<td>Jander et al. 2012 (130)</td>
<td>2200772</td>
<td>Inclusion criteria: Pts presenting with obstructive BPV (of all pts who received a single stented bioprosthetic AV), 01/2007-12/2008; single hospital.</td>
<td>Endpoints: MPG</td>
<td>All 6 pts had received a porcine valve, were hemodynamically stable, and were taking ASA 100 mg/d. Echocardiography showed an increase in MPG early postoperatively from 23.3±4–57.0±10 mm Hg (p &lt;0.001). No adverse events were observed with phenprocoumon. The authors concluded that ‘oral anticoagulation with phenprocoumon is a safe and effective treatment in clinically stable pts with obstructive BPVT, thus obviating repeat valve surgery or thrombolysis’.</td>
</tr>
<tr>
<td>Butnaru, et al</td>
<td>Study type:</td>
<td>Inclusion criteria: 9 pts with clinical or</td>
<td>Endpoints: echocardiographic findings (transvalvular gradient, thrombus)</td>
<td>5 of the 9 pts presented with HF symptoms at 16±12 mo after implantation.</td>
</tr>
</tbody>
</table>
**2013**  
**Pislaru, et al**  
**Study type:** Retrospective  
**Size:** n=9 pts  
**Endpoints:** echocardiographic evidence of valve malfunction were identified after screening 149 consecutive pts who underwent MVR with a bioprosthesis; 2002-2011; single center  
**Results:**  
- Mitral BVPT thrombosis occurred in 9 pts (6%).  
- Of those, 6 pts received anticoagulation with resolution of the echocardiographic findings (reduction in gradients; complete thrombus resolution).  

**2015**  
**Study type:** Retrospective  
**Size:** n=31 pts  
**Endpoints:** Inclusion criteria: pts diagnosed with BPVT; 1997-2013; single institution  
**Results:**  
- Pts treated initially with VKA group (N = 15) were compared to surgery/thrombolysis (N = 17); [non-randomized].  
- VKA and surgery/thrombolysis decreased MPG to a similar extent: VKA group: 13±5–6 ±2 mm Hg in mitral position, 9 ± 3–5 ± 1 mm Hg in tricuspid position and 39±3–24±7 mm Hg in aortic/pulmonary position; non-VKA group: 16 ± 12–5 ± 1 mm Hg in mitral, 10 ± 5–4 ± 1 mm Hg in tricuspid and 57 ± 9–18 ± 6 mm Hg in aortic position (p=0.59 for group effect).  
- NYHA class improved in 11 of 15 pts in the VKA group and 10 of 17 pts in the non-VKA group (p=0.39).  
- No deaths, strokes or recognized embolic events in either group.  

**2015**  
**Makkar, et al**  
**Study type:** Retrospective  
**Size:** n=187 pts  
**Endpoints:** Study analyzed data from 55 pts in a TAVR clinical trial, and 2 single-center registries of 132 pts undergoing either TAVR or surgical AV bioprosthesis implantation  
**Results:**  
- Therapeutic anticoagulation with warfarin (as compared with DAPT), was associated with lower incidence of reduced leaflet motion (0% and 55%, respectively, p=0.01 in the clinical trial; and 0% and 29%, respectively, p=0.04 in the pooled registries).  
- In pts reevaluated with follow-up CT: restoration of leaflet motion was noted in all 11 pts who were receiving anticoagulation and only 1 of 10 pts not receiving anticoagulation (p=0.001).  

**2015**  
**Latib, et al.**  
**Study type:** Retrospective  
**Size:** n=26 pts  
**Endpoints:** Inclusion criteria: Pts with THV thrombosis (from a cohort of 4266 pts undergoing TAVR), 01/2008- 09/2013, 12 centers.  
**Results:**  
- THV thrombosis definition: (1) THV dysfunction 2° to thrombosis diagnosed based on response to anticoagulation therapy, imaging or histopathology; or (2) mobile mass detected on THV suspicious of thrombus, irrespective of dysfunction and in absence of infection.  
- 26 (0.61%) pts had THV thrombosis after TAVR implantation; median time to thrombosis post-TAVR: 181 d (interquartile range, 45-313); most common clinical presentation: exertional dyspnea (65%).
Anticoagulation resulted in a significant decrease in AV MPG in 88% of pts within 2 mo.

The authors concluded: ‘THV thrombosis is a rare phenomenon that was detected within the first 2 y after TAVR and usually presented with dyspnea and increased gradients. Anticoagulation seems to have been effective and should be considered even in pts without visible thrombus on echocardiography.”

De Marchena, et al. 2015

| Study type: multinational registry (data collected retrospectively and retrospectively) | Inclusion criteria: Either CoreValve or Edwards SAPIEN devices are included | Endpoints: Procedural success; adverse procedural outcomes; post-VIV gradients; 30 d mortality and NYHA III; 1-y survival. | The was the first large, comprehensive evaluation of a transcatheter approach for failed surgically inserted aortic bioprostheses |
| Size: n=23052028 | Exclusion criteria: N/A |                                                                 | Pts receiving VIV in the stenosis group had worse 1-y survival (76.6%) in comparison with the regurgitation group (91.2%) and the combined group |

Data Supplement 9. Clinical Outcomes With VIV Procedures (Sections 11.7.3 and 11.8.3)
### Study type: multinational registry (data retrospectively for cases performed before registry initiation and prospectively)
- **Size:** n=459 pts

### Inclusion criteria: Pts with degenerated bioprosthetic valves undergoing VIV implantation (2007-2013)

### Exclusion criteria: VIV procedures performed using other devices than the self-expandable CoreValve (Medtronic) and balloon expandable Edwards SAPIEN devices (Edwards Lifesciences), or implanted in positions other than the aortic position.

### Endpoints: Survival, Stroke, and NYHA functional class. [Major clinical endpoints were assessed according to the VARC criteria]

### Results:
- 1-y Kaplan-Meier survival rate: 83.2% (95% CI: 80.8–84.7%).
- Within 1 mo: death: 7.6%; major stroke 1.7%; Survivors with NYHA I/II: 92.6%.

- Implanted devices included both balloon- and self-expandable valves.
- Pts with at least a moderate degree of both stenosis and regurgitation were included in the combined group.
- Pts in the stenosis group had worse 1-y survival (76.6%) in comparison with the regurgitation group (91.2%) and the combined group (83.9%) (p=0.01).
- Factors associated with 1-y mortality: small surgical bioprosthesis (≤21 mm) & baseline stenosis (vs. regurgitation).

---

### Study type: Case series
- **Size:** n=24 pts (of whom 10 pts had VIV in the aortic position).

### Inclusion criteria: 24 high-risk pts with failed bioprosthetic valves (n=10 were in the aortic position).

### Exclusion criteria: N/A

### Endpoints: Procedural success and complications, 30-d mortality.

### Results:
- In the 10 pts with VIV in the aortic position: VIV implantation was uniformly successful with excellent improvement in valve function, no major morbidity. 30 d mortality: 0%.

- Transcatheter VIV implantation is a reproducible option for the management of selected pts with bioprosthetic valve failure.
- The aortic, pulmonary, mitral, and tricuspid tissue valves may be amenable to this approach.

---

### Study type: Prospective web-based multicenter registry.
- **Size:** n=24

### Inclusion criteria: Pts treated with the VIV technique for severe PVL following TAVR.

### Exclusion criteria: N/A

### Endpoints: Major adverse cerebrovascular and cardiac events and prosthesis performance at 30 d and midterm follow-up.

### Results:
- The VIV technique was used in 3.6% of all 663 TAVR pts.

- The VIV group was a subpopulation from 663 consecutive pts who underwent TAVR with the 18-F CoreValve ReValving System (Medtronic, Inc., Minneapolis, Minnesota) at 14 centers across Italy.
- The study demonstrated that transcatheter aortic VIV after TAVR using the 3rd-generation CoreValve ReValving System is feasible, safe, and
In the transcatheter aortic VIV group:
- 30 d major adverse cerebrovascular and cardiac events: 0%.
- 30-d mortality: 0%.
- 12 mo major adverse cerebrovascular and cardiac events: 14.1%.
- 12 mo mortality: 13.7%.

Thus, following TAVR, the VIV technique offers a viable therapeutic option in pts with acute significant PVL without recourse to emergent surgery.

</tr>
<tr>
<td>Endpoints:</td>
<td>Procedural success, 30-d/1-y mortality, mean gradient, PVL.</td>
</tr>
<tr>
<td>Results:</td>
<td>Procedural success: 90%. Mortality at 30 ds and 1 y: 14.3% and 24%, respectively. After successful procedure: Mean gradient reduced from 37 ± 12 mm Hg–13 ± 5 mm Hg (p&lt;0.01); AVA increased from 0.64 ± 0.14–1.55 ± 0.27 cm² (p&lt;0.01); PVL was none in 4 pts, mild in 13 pts, and moderate in 2 pts. At 1-y follow-up: 1 pt had moderate and the others had mild/no PVL.</td>
</tr>
<tr>
<td>Study type:</td>
<td>AR was paravalvular in 18 pts and transvalvular in the remaining 3 pts. At one-y, the mean transaortic gradient was 15 ± 4 mm Hg, which was higher than in pts undergoing conventional TAVR (11 ± 4 mm Hg, p=0.02). Transcatheter VIV procedure in a failed THV is feasible and results in satisfactory short- and mid-term outcomes.</td>
</tr>
</tbody>
</table>
### Bapat, 2012 (141) 23140962
**Study type:** single-center case-series  
**Size:** n=23  
**Inclusion criteria:** pts undergoing a VIV procedure with the Edwards Sapien valve to treat a failing AV bioprosthesis (2008-2011).  
**Exclusion criteria:** N/A  
**Endpoints:** procedural success, short-term mortality, gradient.  
**Results:**  
- Procedural success: 100% (1 pt needed a second valve).  
- Mean gradient was reduced from 31.2 ± 17.06 mm Hg– 9.13 ± 4.9 mm Hg.  
- In-hospital and/or 30-d mortality: 0%.  
**Note:** 13 pts had predominantly bioprosthetic stenosis, and the remaining had mostly regurgitation. Most VIV procedures (21/23) were performed via the transapical route. The transcatheter VIV is a safe and feasible alternative to treat high-risk pts with failing aortic bioprostheses.

### Linke, et al 2012 (142) 23048050
**Study type:** single-center observational study  
**Size:** n=27  
**Inclusion criteria:** Consecutive symptomatic pts with failing AV bioprosthesis & aged ≥ 65 y & logistic EuroSCORE ≥10%; an inner diameter of the previously implanted bioprosthesis: 18.5-27 mm; ascending aorta diameter ≤ 45 mm above the sinotubular junction; access vessels ≥6 mm.  
**Exclusion criteria:** N/A  
**Endpoints:** procedural and short-term outcomes, 30-d mortality.  
**Results:**  
- Using VARC criteria:  
  - major stroke: 7.4%.  
  - life-threatening bleeding: 7.4%.  
  - kidney failure stage III: 7.4%. Major access site complication 11.1%.  
- 30-d mortality: 7.4%.  
**Note:** Failure of bioprosthetic valves may be safely corrected by TF implantation of MCV, irrespective of the failure mode and the bioprosthesis valve type. VIV implantation can be performed completely percutaneously under conscious sedation. VIV implantation results in marked, instantaneous improvement in hemodynamics, which remains evident at long-term follow-up.

### Ihlberg, L et al. 2013 (143) 23998786
**Study type:** multicenter registry, retrospective.  
**Size:** 45  
**Inclusion criteria:** All transcatheter VIV procedures the Nordic countries between 2008 and 2012.  
**Exclusion criteria:** N/A  
**Endpoints:** Periprocedural and postoperative outcomes (assessed using the VARC criteria).  
**Results:**  
- No intraprocedural mortality.  
- Technical success: 95.6%.  
- All-cause 30-d mortality: 4.4%.  
- 30-d major complications: stroke: 22%, Periprocedural MI: 4.4%, major vascular complication: 2.2%.  
- At 1 mo, all but 1 pt had either no or mild PVL.  
- 1 y survival: 88.1%.  
**Note:** The type of failure was stenosis/ combined in 58% & regurgitation in 42% of cases. The SAPIEN/XT (Edwards LifeSciences, Irvine, CA) and CoreValve (Medtronic Inc, Minneapolis, Minn) systems were used. Access (transapical, transfemoral, transaortic, and subclavian). Mean follow-up: 14.4 mo. Transcatheter VIV is widely performed in most centers in the Nordic countries. The short-term results were excellent in this high-risk pt population, demonstrating a low incidence of device- or procedure-related complications.

### Camboni, et al 2015 (144) 25681576
**Study type:** prospective single-center registry  
**Size:** 31  
**Inclusion criteria:** Pts undergoing VIV procedure at single institution since 2009.  
**Exclusion criteria:** TAVR pts not undergoing VIV (608 pts)  
**Endpoints:** Procedural success, 30-d survival, post-VIV regurgitation.  
**Results:**  
- Procedural success: 88%.  
- Post-procedural regurgitation: trace in 23% and moderate in 13% of pts.  
- 30-d survival: 77% with a significantly improved NYHA class of 1.79 ± 0.58 (p=0.001).  
**Note:** Pts were provided with 5 Medtronic CoreValues, 15 Edwards SapienXT, 1 Edwards Sapien 3, 7 Medtronic Engager, and 3 Symetis Acurate TA valves.The left main stem was occluded in 1 pt (Sapien XT 26 in a Mitroflow 25 mm) who underwent emergent Jeopardizing coronary blood flow was likely in stenotic and calcified bioprostheses, particularly in tubelike aortic sinuses. The investigators concluded that ‘Planning, imaging, and the use of valves...

<td>pts with aortic (n= 42) and mitral (n= 31) bioprosthetic valve dysfunction undergoing transcatheter VIV implantation (2007-2013).</td>
<td>30-d outcomes; mid/long-term survival, NYHA</td>
<td>This has the longest follow-up (Median follow-up: 2.52 y with a maximum of 8 y) of all registries transcatheter aortic and mitral VIV implantation. Only Edwards balloon-expandable transcatheter valves (Edwards Lifesciences Inc., Irvine, California) were used. The small surgical valve size (19 and 21 mm) was an independent risk factor.</td>
</tr>
</tbody>
</table>
### Exclusion criteria: N/A

**At 30 d:**
- All-cause mortality: 1.4%, Disabling stroke 1.4%,
- Life-threatening bleeding: 4.1%,
- AKI requiring hemodialysis 2.7%,
- Coronary artery obstruction requiring intervention 1.4%.

At 2-y follow-up, 82.8% of aortic VIV pts were in NYHA functional class I/II.

Estimated survival rates were 88.9%, 79.5%, 69.8%, 61.9%, and 40.5% at 1, 2, 3, 4, and 5 y, respectively.

---

*Selective contemporary studies of transcatheter VIV procedures for failed bioprosthetic valves (excluding small studies with <20 pts).*

---

- Transcatheter VIV procedures can be performed safely with a high success rate and minimal early mortality and morbidity, and provides encouraging mid/long-term clinical outcomes.

<td>To evaluate the predictors of outcome and to establish whether early surgery is associated with reduced mortality</td>
<td>Prospective multicenter cohort study</td>
<td>116</td>
<td>S. aureus IE alone; NVE 83%, PVE 17%; surgery 47%</td>
<td>Registration of epidemiological, clinical, microbiological and other laboratory features, echocardiography data, and treatment strategy. Antibiotic treatment. In-hospital mortality rate was 26%, and the 36-mo survival rate was 57%. Surgical group mortality was 16% vs. 34% in the medically treated group (p&lt;0.05) In unadjusted analyses, early surgery performed in 47% of pts was associated with lower in-hospital mortality (16% vs. 34%; p=0.034) and with better 36-mo survival (77% vs. 39%; p&lt;0.001).</td>
<td>Multivariate analyses identified comorbidity index, HF, severe sepsis, prosthetic valve IE, and major neurologic events as predictors of in-hospital mortality. Severe sepsis and comorbidity index were predictors of overall mortality. After adjustment of baseline variables related to mortality, early surgery revealed that surgery was associated with decreased mortality (HR: 0.27; 95% CI: 0.13–0.55). A HX of DM (HR: 4.81; 95% CI: 2.41–9.62), the presence of chronic IV catheters at the beginning of the episode (HR: 2.65; 95% CI: 1.31–5.33), and with increased mortality.</td>

<td>To examine the association between the timing of valve surgery after IE dx and 6-mo mortality among pts with left-sided IE</td>
<td>Retrospective single-center cohort propensity analysis</td>
<td>546</td>
<td>NVE alone; surgery 24%</td>
<td>The association between time from IE dx to surgery and all-cause 6 mo mortality was assessed using Cox proportional hazards modeling after adjusting for the propensity score (to undergo surgery 0–11 d vs. 11 d, median time, after IE dx).</td>
<td>The median time between IE dx and surgery was 11 d (range 1–30). Using Cox proportional hazards modeling, propensity score and longer time to surgery (in d) were associated with unadjusted HRs of (1.15, 95% CI: 1.04–1.28, per 0.10 unit change; p=0.009) and (0.93; 95% CI: 0.88–0.99, per d; p=0.03), respectively. In multivariate analysis, a longer time to surgery was associated with an adjusted HR: (0.97; 95% CI: 0.90–1.03). The propensity score and time from dx to surgery had a correlation coefficient of r=0.63, making multicollinearity an issue in the multivariable model.</td>

<tr>
<td>Kang, 2012 (179) 22738096</td>
<td>To compare clinical outcomes of early surgery and conventional treatment in pts with IE.</td>
<td>Prospective randomized trial at 2 centers with intention to treat analysis. 76 Left-side NVE and high risk of embolism to early surgery (49%) vs. conventional treatment (51%). Pts were randomly assigned in a 1:1 ratio to the early-surgery group or the conventional-treatment group with the use of a Web-based interactive response system. The protocol specified that pts who were assigned to the early-surgery group should undergo surgery within 48 h after randomization. Pts assigned to the conventional-treatment group were treated according to AHA guidelines, and surgery was performed only if complications requiring urgent surgery developed during medical treatment or if symptoms persisted. The 1st endpoint (composite of in-hospital death and embolic events that occurred within 6 wk after randomization) occurred in 1 pt (3%) in the early surgery group as compared with 9 (23%) in the conventional-treatment group (HR: 0.10; 95% CI: 0.01–0.82; p=0.03). There was no significant difference in all-cause mortality at 6 mo in the early-surgery and conventional-treatment groups (3% vs 5%, respectively; HR: 0.51; 95% CI: 0.05–5.66; p=0.59). The rate of the composite endpoint of death from any cause, embolic events, or recurrence of IE at 6 mo was 3% in the early-surgery group and 28% in the conventional-treatment group (HR: 0.08; 95% CI: 0.01–0.65; p=0.02). As compared with conventional treatment, early surgery in pts with IE and large vegetations significantly reduced the composite endpoint of death from any cause and embolic events by effectively decreasing the risk of systemic embolism.</td>

To establish guidelines for the surgical treatment of pts with IE who have cerebrovascular complications

Retrospective study of 181 pts with cerebral complication among 2523 surgical cases of IE

Predominately left sided IE; 37.5% PVE and 62.5% NVE with neurological complications of IE

Questionnaire consisting of 2 parts: (1) Each center was asked for a summary of the number and outcome of pts with IE according to the types of IE 1 (active/healed and native valve/prosthetic valve) and the presence of cerebral complications; (2) the other portion inquired about each pt with cerebral complications, asking for details such as age, gender, AF, anticoagulant therapy, diseased valve, organism, effectiveness of antimicrobial therapy, reason for early cardiac operation, interval between the onset of symptoms and the cardiac operation, type of cerebral complication, cerebral aneurysm, prior cerebral surgery, severity, influence of operation on cerebral damage, and outcome.

To study the influence of cardiac surgery on preoperative cerebral complications, we analyzed the interval between the onset of cerebral complications and performance of the cardiac operation, as well as other preoperative variables. The effectiveness of antimicrobial therapy was ranked in 3 grades (1 = ineffective, 2 = effective, and 3 = well controlled). A correlation between the interval and the exacerbation of cerebral complications was evaluated by means of the Spearman rank correlation coefficient. The intervals were then classified in several groups, and variability between the groups for the exacerbation was estimated by Scheffe’s F procedure for post-hoc comparisons, according to the Kruskal-Wallis test. To analyze the risk factors affecting exacerbation of cerebral complications, we expressed preoperative variables as mean ± standard error. The difference between the groups with and without exacerbation was tested for significance by the unpaired t test, and incidence was expressed as percentage of pts having the variable compared with the entire group of pts and then compared by χ2 analysis. Moreover, all variables and incidence (transformed to continuous variables) were estimated by stepwise regression analysis. Statistical significance was accepted at a p level of <0.05. These analyses were done with the Stat View system (Abacus Concepts, Inc., Berkeley, Calif.).

The rate of exacerbation of cerebral complications decreased to 10% in pts who underwent surgical treatment more than 15 d after cerebral infarction and to 2.3% in those operated on more than 4 wk later. Preoperative risk factors were severity of cerebral complications, interval from onset of symptoms to operation, and uncontrolled HF as the indication for cardiac surgery. More than 15 d after cerebral hemorrhage, the risk of the progression of cerebral damage is still significant, and this risk persists even 4 wk later.

Assess the incidence of neurological complications in pts with infective endocarditis, the risk factors for their development, their influence on the clinical outcome, and the impact of cardiac surgery

Retrospective analysis of prospectively collected data on a multicenter cohort

1345 pts Consecutive Left sided endocarditis cases from 8 Centers in Spain

Specific variables from registries were analyzed including the date of IE dx; pts age and sex; type of endocarditis (native or prosthetic); location and size of vegetations on echocardiography; infecting microorganism; date, type, and extent of neurological complications; anticoagulant therapy given; date of the start of antimicrobial treatment; date of surgery (if performed); and outcome.

Determine the risk factors associated with the development of all neurological complications

Predictors of neurological complications were vegetation size ≥3 cm (HR: 1.91; 95% CI: 1.07–3.43; p=0.029), S aureus as the cause of IE (HR: 2.47; 95% CI: 1.94–3.15; p<0.001), anticoagulant therapy at IE dx (HR: 1.31; 95% CI: 1.00–1.72; p=0.048), and MV involvement (HR: 1.29; 95% CI: 1.02–1.61; p=0.03). Further analysis showed that elderly pts (≥70 y) had lower complication rates than younger ones, and only hemorrhagic events showed statistical significance (HR: 0.36; 95% CI: 0.16–0.83; p=0.014). Anticoagulant treatment was particularly associated with cerebral hemorrhage (HR: 2.71; 95% CI: 1.54–4.76; p=0.001).
Examine the relationship between the timing of surgery after stroke and the incidence of in-hospital and 1-y mortalities.

Post-hoc review of the International Collaboration on Endocarditis – Prospective Cohort Study of 857 pts with definite IE who were admitted to 64 centers June 2000–December 2006. Multivariate logistic regression and Cox regression analyses were performed to estimate the impact of early surgery on hospital and 1-y mortality after adjustments for other significant covariates.

After adjustment for other risk factors, early surgery was not significantly associated with increased in-hospital mortality rates (OR: 2.308; 95% CI: 0.942–5.652). Overall, probability of death after 1-y follow-up did not differ between 2 treatment groups (27.1% in early surgery and 19.2% in late surgery group, p=.328; adjusted HR: 1.138; 95% CI: 0.802–1.650).
