Background—Therapeutic angiogenesis is thought to be beneficial for serious ischemic diseases. This investigation was designed to establish a simple and practical procedure applicable to therapeutic angiogenesis.

Methods and Results—When cultured skeletal muscle cells were electrically stimulated at a voltage that did not cause their contraction, vascular endothelial growth factor (VEGF) mRNA was augmented at an optimal-frequency stimulation. This increase of VEGF mRNA was derived primarily from transcriptional activation. Electrical stimulation increased the secretion of VEGF protein into the medium. This conditioned medium then augmented the growth of endothelial cells. The effect of electrical stimulation was further confirmed in a rat model of hindlimb ischemia. The tibialis anterior muscle in the ischemic limb was electrically stimulated. The frequency of stimulation was 50 Hz and strength was 0.1 V, which was far below the threshold for muscle contraction. After a 5-day stimulation, there was a significant increase in blood flow within the muscle. Immunohistochemical analysis revealed that VEGF protein was synthesized and capillary density was significantly increased in the stimulated muscle. Rats tolerated this procedure very well, and there was no muscle contraction, muscle injury, or restriction in movement.

Conclusions—We propose this procedure as a simple and practical method of therapeutic angiogenesis. (Circulation. 1999;99:2682-2687.)

Key Words: electrical stimulation • growth substances • angiogenesis

Arterial occlusive diseases cause serious ischemic diseases in various organs, such as the heart, brain, and leg, and therapeutic angiogenesis is thought to be beneficial for such conditions.1 Local administration of recombinant angiogenic growth factors, such as basic fibroblast growth factor (bFGF) and vascular endothelial growth factor (VEGF), salvaged ischemic areas of myocardium and hindlimb in animal models.2–6 However, the clinical application requires large amounts of these recombinant proteins and is not feasible at this time. Instead of recombinant proteins, use of gene therapy, i.e., in vivo transfection of angiogenic growth factor gene, has been attempted to treat these diseases. In particular, the clinical trial of intramuscular gene transfer of naked plasmid DNA encoding human VEGF165 is progressing in the United States for the treatment of ischemic limbs.7

Methods

Cell Culture and Electrical Stimulation In Vitro

Murine skeletal muscle cell line C2C12 cells were obtained from Riken Cell Bank; rat aortic smooth muscle cells from Hanno Research Center, Taiho Pharmaceutical Co Ltd; and human pulmonary artery smooth muscle cells from Kurabo. Cells were routinely cultured on plastic dishes in DMEM (Nissui Pharmaceutical Co, Ltd) containing 10% FCS (Summit Biotechnology). Bovine capillary ECs (BCECs) were obtained from Dr T. Tamaoki (Kyowa Hakko Kogyo Co, Ltd) and were grown in DMEM containing 10% FCS (Summit Biotechnology). BCECs were grown in DMEM containing 10% FCS as described previously.11 All primary cultures of passage <6 were used in following experiments.
Electrical Stimulation of Cells In Vitro

Before the following experiments, cells were preincubated for 24 hours in DMEM containing 0.1% BSA. Confluent cultures were electrically stimulated at 1.0 V of stimulus strength and at indicated frequencies (Hz) for an indicated period, according to the method described by Brevet and Pinto.  

Northern Blot Analysis

Northern blot analysis was carried out as described previously. Brieﬂy, total RNA was extracted by the Acid Guanidium-Phenol-Chloroform method and fractionated on a 1% agarose gel containing 2.2 mol/L formaldehyde. The blots were then prepared by transfer onto a nylon ﬁlter (Hybond N°, Amersham). The ﬁlter was hybridized with a 32P-labeled probe in hybridization solution for 24 hours at 42°C. After the hybridization, the ﬁlter was washed in 2×SSC and 0.1% SDS at 60°C and then in 0.2×SSC and 0.1% SDS at 60°C. Autoradiography was carried out on an imaging plate, and autoradiograms were analyzed with an FLA 2000 image analyzer (Fuji).

Measurement of VEGF Protein in Conditioned Medium

C2C12 cells in DMEM containing 0.1% BSA were electrically stimulated for 24 hours at 1.0 V and 50 Hz, and the medium was collected. VEGF protein in the medium was measured by Quantikine-M ELISA kit (R&D Systems) according to the manufacturer’s protocol.

Effect of Medium Conditioned by Electrical Stimulation on the Growth of BCECs

BCECs (5×10^4) were plated on plastic dishes in DMEM with 10% FCS and incubated for 6 hours to allow attachment to the dish. The culture medium was replaced with either 100% conditioned medium, fresh medium (DMEM containing 0.1% BSA), or fresh medium supplemented with 10 ng/mL of recombinant human VEGF. Cell numbers were counted after 48 hours of incubation.

Electrical Stimulation In Vivo

All animal studies were performed according to a protocol approved by the Animal Experiment Committee of our institute. Male Sprague-Dawley rats (300 to 350 g body weight) were used. The animals were anesthetized with light ether sedation and subcutaneous injection of pentobarbital sodium (50 mg/kg) (Nembutal, Abbott Laboratories). The operation for hindlimb ischemia was performed in the left hindlimb of each animal. Thereafter, the specimens were stained by the ABC method (Elite, Vector Laboratories, Inc).

For detection of VEGF protein, muscle specimens were fixed with 10% formaldehyde, preincubated with 1% BSA for 30 minutes, and then incubated with rabbit polyclonal anti-VEGF antibody (1 μg/mL) (Santa Cruz Biotechnology) for 30 minutes at room temperature. Thereafter, the specimens were stained by the ABC method (Elite, Vector Laboratories, Inc).

Determination of Capillary Density

Numbers of capillaries and muscle ﬁbers were counted in at least 8 different ﬁelds, and capillary density was obtained by the calculation of capillary number/fiber area.

Calculations and Statistical Analysis

The statistical signiﬁcance of differences in the results was evaluated by unpaired ANOVA, and a value of P<0.05 was accepted as statistically signiﬁcant.

Results

Induction of VEGF mRNA by Electrical Stimulation

To determine whether electrical stimulation affects the expression of VEGF mRNA, we exposed cultured skeletal muscle cells to electrical pulse stimulation for 24 hours at various frequencies and 1.0 V strength, which did not cause their contraction or interfere with their spontaneous contraction. Northern blot analysis revealed that VEGF mRNA was augmented at speciﬁc frequencies. In murine skeletal muscle cell line C2C12 cells, the expression of VEGF mRNA was signiﬁcantly augmented at the narrow range of frequencies around 50 Hz (Figure 1A). This frequency of electrical stimulation augmented the expression of VEGF mRNA in primary culture of rat skeletal muscle cells as well (data not shown). Although 50-Hz electrical stimulation seemed to be optimal for the expression of VEGF mRNA in skeletal muscle cells, it did not augment the expression of VEGF mRNA in rat aortic smooth muscle cells (Figure 1B) or human ﬁbroblasts (data not shown). Instead, the expression of VEGF mRNA was increased at 48-fold in skeletal muscle cells and 4.5-fold in smooth muscle cells at the 8-hour time point at the proper frequency. To exclude the possibility that substances that might be released from the electrodes into the medium affected the expression of VEGF mRNA, we electrically agitated the medium and exposed it to the cells. We did not see any augmentation of the expression of VEGF mRNA by this procedure (data not shown). The expression of VEGF receptor-2 (KDR/Fk-1) mRNA in BCECs was not affected by electrical stimulation at various frequencies (Figure 1C).
The level of expression of VEGF mRNA was determined by the transcription rate of VEGF gene and/or the stability of VEGF mRNA. Therefore, we used actinomycin-D (Act-D) to evaluate the stability of VEGF mRNA. As shown in Figure 2, the half-lives of VEGF mRNA, which were calculated by drawing the best-fit linear curve on a log-linear plot of the percentage of RNA remaining versus time in Act-D–treated cells, were 0.99 hour for electrically stimulated and 1.12 hour without electrical stimulation. Thus, the electrical stimulation did not affect the stability of VEGF mRNA, indicating that the augmentation of VEGF mRNA by electrical stimulation was at the transcriptional level.

Next, we examined the effect of transient electrical stimulation. Cells were exposed to 2 hours of electrical stimulation, and then the total RNA was harvested at 22 hours after the transient stimulation. The results showed that the induction of VEGF mRNA was observed 22 hours after the transient stimulation, and the level of its expression was almost identical to that of the continuous electrical stimulation for 24 hours (Figure 3). Because VEGF mRNA returned to the basal level by 46 hours after a 2-hour electrical stimulation, the second stimulation could increase VEGF mRNA to a level comparable to the first stimulation. Thus, the transient electrical stimulation was equally effective and was repeatable.

**Synthesis and Secretion of VEGF Protein**

The synthesis and secretion of VEGF protein into the medium was analyzed by ELISA. VEGF in the medium of both C2C12 cells and rat aortic smooth muscle cells was increased by electrical stimulation (Figure 4A). These stimulatory effects were observed to increase VEGF mRNA at the same specific frequencies in these cells. The elevation of VEGF protein in the medium was observed as early as 12 hours and reached its peak at 48 hours (Figure 4B). The conditioned medium of electrical stimulation augmented the growth of BCECs as much as the medium supplemented with 10 ng/mL of human recombinant VEGF (Figure 4C). Although proteins other than VEGF might also be responsible for the growth of BCECs, the concentration of VEGF in conditioned medium determined by ELISA suggested that most of the effects on the growth of BCECs were derived from VEGF.

**Rat Model of Ischemic Hindlimb**

We used the ischemic hindlimb animal model to investigate whether electrical stimulation might induce angiogenesis and increase blood flow in an ischemic limb. Blood flow was measured in TA muscles of ischemic and contralateral limbs. The percentage of blood flow in experimental muscles versus contralateral muscles is shown in Figure 5. Blood flow in the ischemic limb on day 7 after the left FA excision was...
significantly lower than that in the contralateral limb as well as in the sham-operated animals. Whereas blood flow in the ischemic limb on day 14 after the left FA excision did not increase without any stimulation, continuous electrical stimulation significantly increased blood flow in the TA muscle of the ischemic limb. In addition, rats tolerated this procedure very well, and there was no muscle contraction, muscle injury, or restriction in movement.

Immunostaining of TA muscles with polyclonal anti-VEGF antibody revealed a significant increase of VEGF protein in the muscle fibers of electrically stimulated TA muscles compared with unstimulated muscles or contralateral
TA muscles (Figure 6). This increase of VEGF protein was found only in the area between the electrodes on TA muscle. Capillary density of the stimulated muscles was increased ≈2.5-fold compared with the contralateral muscles, whereas unstimulated animals as well as sham-operated animals had no significant difference between ischemic and contralateral muscles (Figure 7).

### Discussion

Our present study demonstrated that direct electrical stimulation of cultured skeletal muscle cells induced the expression of VEGF. Moreover, the low-voltage electrical stimulation of ischemic skeletal muscle augmented de novo synthesis of VEGF protein in the muscle, induced regional angiogenesis, and restored blood flow in ischemic muscle. Electrical stimulation at 100 Hz did not increase the capillary density in animals (data not shown). This also implied that metabolic activation could not simply explain the augmentation of VEGF synthesis in the muscle. It was interesting that the optimal electrical frequency seemed to vary between individual cell types, i.e., 50 Hz for skeletal muscle cells and 24 Hz for smooth muscle cells. Frequency-dependent gene expression or protein synthesis in insulin-like growth factor-2 of osteosarcoma cells\(^1\) and constitutive NO synthase of cardiomyocytes\(^2\) have been described previously. Although the mechanism of the frequency dependence of VEGF induction is obscure at the moment, this characteristic will allow us to restrict the induction of VEGF to skeletal muscle. Two reports describe the augmentation of VEGF synthesis after in vivo electrical stimulation: in one, skeletal muscle was stimulated at 10 Hz and 3 to 4 V, which induced muscle contraction\(^3\); in the other, a motor nerve was stimulated at 6 to 10 Hz, which also induced muscle contraction.\(^4\) Because the frequencies used were far below the optimal value for VEGF induction in skeletal muscle, the effects of these studies on the synthesis of VEGF might not be derived from muscle contraction.

Induction of angiogenesis in skeletal muscle by electrical stimulation has been described.\(^5\)–\(^9\) However, the aim of electrical stimulation in those reports was to produce maximal muscle contraction. Indeed, they used an electrical strength of >2.0 V for the stimulation. It was hypothesized that hypoxia caused by muscle contraction was relevant to the increase of capillary density of skeletal muscles in their model.\(^6\) Nevertheless, strenuous electrical stimulation might be harmful, fail to restore blood flow, increase muscle atrophy, and worsen fatigue.\(^7\) Here, we used 0.1 V of electrical strength for stimulation of rat TA muscle. This strength of electrical stimulation was 10% of the threshold of muscle contraction and was well tolerated. We therefore propose that this procedure can be applicable as a simple and practical method of therapeutic angiogenesis.

Transcutaneous electrical nerve stimulation (TENS) has been used in the clinical field for pain control. Interestingly, TENS is highly effective in acute musculoskeletal pain as well as pain from peripheral vascular disease and from angina pectoris. However, the reasons for pain relief from TENS are largely unknown at present.\(^8\) Because TENS is primarily nerve stimulation and a high frequency in the range of 60 to 100 Hz is generally considered conventional for this treatment, it is not known whether conventional TENS induces regional angiogenesis.

Our results indicated that electrical stimulation augmented VEGF mRNA via transactivation of the VEGF gene. However, the mechanism of how low-voltage electrical stimulation induces the expression of VEGF gene is unknown. VEGF can be induced by various stimuli. Among them, hypoxia is thought to be one of the most important stimuli for the expression of the VEGF gene. Transactivation of the VEGF gene in hypoxia is mediated by hypoxia-inducible factor-1, which binds to the hypoxia responsive element in the 5' flanking region of the VEGF gene. Heme-containing protein works as a sensor of oxygen, and hypoxia, as well as nickel or cobalt, induces hypoxia-inducible factor-1 by activating this sensing system.\(^9\) We used nickel to mimic the hypoxic condition and found that the electrical stimulation reinforced the expression of VEGF in the hypoxic condition (data not shown). This notion is consistent with the in vivo experimental results showing that electrical stimulation effectively augmented VEGF synthesis in the ischemic skeletal muscle.

Gene therapy using VEGF is thought to be relevant for therapeutic angiogenesis, and a clinical trial is now progressing in the United States.\(^7\) However, gene therapy is not always available. The important point on this issue is that the expression of VEGF is not restricted to a specific cell type; rather, it is synthesized by a variety of cell types surrounding ECs. If one could force cells in the ischemic area to synthesize a sufficient amount of endogenous VEGF protein, synthesized VEGF would promote local angiogenesis and salvage the ischemic area. Our results reinforce the above idea. We propose that it would be valuable to consider this procedure for clinical application.
