AHA/ACC/SCAI/ACS/ADA Science Advisory

Prevention of Premature Discontinuation of Dual Antiplatelet Therapy in Patients With Coronary Artery Stents

A Science Advisory From the American Heart Association, American College of Cardiology, Society for Cardiovascular Angiography and Interventions, American College of Surgeons, and American Dental Association, With Representation From the American College of Physicians*

Cindy L. Grines, MD, FACC; Robert O. Bonow, MD, FAHA, FACC; Donald E. Casey, Jr, MD, MPH, MBA, FACP; Timothy J. Gardner, MD, FAHA, FACC, FACS; Peter B. Lockhart, DDS, FDS RCSEd; David J. Moliterno, MD, FAHA, FSCAI, FACC; Patrick O’Gara, MD, FAHA, FACC; Patrick Whitlow, MD, FAHA, FACC

Abstract—Dual antiplatelet therapy with aspirin and a thienopyridine has been shown to reduce cardiac events after coronary stenting. However, many patients and healthcare providers prematurely discontinue dual antiplatelet therapy, which greatly increases the risk of stent thrombosis, myocardial infarction, and death. This advisory stresses the importance of 12 months of dual antiplatelet therapy after placement of a drug-eluting stent and educating the patient and healthcare providers about hazards of premature discontinuation. It also recommends postponing elective surgery for 1 year, and if surgery cannot be deferred, considering the continuation of aspirin during the perioperative period in high-risk patients with drug-eluting stents. (Circulation. 2007;115: &NA;–&NA;)

Key Words: AHA Scientific Statements ■ thrombosis ■ myocardial infarction ■ stents ■ myocardial stunning

After placement of a bare-metal stent, thienopyridines (clopidogrel [Plavix, sanofi-aventis, Bridgewater, NJ] or ticlopidine [Ticlid, Hoffmann-La Roche Inc, Nutley, NJ]), in combination with aspirin therapy, have been shown to dramatically reduce the incidence of early major adverse cardiac events after stent placement compared with aspirin alone or in combination with warfarin (Table 1).1 In addition, the use of thienopyridine plus aspirin for up to 1 year after non–ST-segment-elevation acute coronary syndromes is known to decrease the incidence of ischemic cardiovascular events and is recommended in the American College of Cardiology/American Heart Association practice guidelines for the treatment of patients undergoing percutaneous coronary intervention and for the medical treatment of patients with non–ST-segment–elevation acute coronary syndromes.2–4 Despite these benefits, antiplatelet therapy is sometimes prematurely discontinued within the first year after stent implantation, either by the patient or by a healthcare provider who may not realize these benefits or the potentially severe consequences of antiplatelet therapy cessation. The leading adverse event associated with early antiplatelet...
discontinuation is stent thrombosis, and the majority of these events lead to acute myocardial infarction (MI) or death. Therefore, the American Heart Association, working with the American College of Cardiology, the Society for Cardiovascular Angiography and Interventions, the American College of Physicians, the American College of Surgeons, and the American Dental Association, commissioned this advisory to emphasize the potential complications of premature discontinuation of thienopyridine therapy and to address potential strategies to minimize this occurrence.

**Dual Antiplatelet Therapy for Prevention of Ischemic Cardiovascular Events and Stent Thrombosis**

Current American College of Cardiology/American Heart Association/Society for Cardiovascular Angiography and Interventions recommendations for the prevention of stent thrombosis after coronary stent implantation state that, at a minimum, patients should be treated with clopidogrel 75 mg and aspirin 325 mg for 1 month after bare-metal stent implantation, 3 months after sirolimus drug-eluting stent (DES) implantation, 6 months after paclitaxel DES implantation, and ideally, up to 12 months if they are not at high risk for bleeding. These recommendations were based on the antiplatelet regimen used in trials that were conducted to obtain US Food and Drug Administration approval (low-risk lesions in low-risk patients).

In the current era of dual antiplatelet therapy, the average reported occurrence of subacute stent thrombosis is 1%. The timing of thrombosis appears to be delayed in DES. Late (1 to 12 months) stent thrombosis was not readily apparent with bare-metal stents yet was reported to occur in 0.19% of patients in a large DES registry. Predictors of late stent thrombosis have included stenting of small vessels, multiple lesions, long stents, overlapping stents, ostial or bifurcation lesions, prior brachytherapy, suboptimal stent result (underexpansion, malapposition, or residual dissection), low ejection fraction, advanced age, diabetes mellitus, renal failure, acute coronary syndrome, and premature discontinuation of antiplatelet agents.5,6,14

On December 7–8, 2006, the US Food and Drug Administration convened an advisory panel meeting to discuss stent thrombosis and the overall safety of DES. They concluded that there appears to be a numerical excess of late stent thrombosis with DES, but the magnitude is uncertain; and the off-label use of DES, as with bare-metal stents, is associated with increased risk when compared with on-label use. The panel also agreed that, in the future, new DES studies should have longer follow-up, enroll greater numbers of patients, and include stent thrombosis as a study end point. The advisory panel concurred with the joint clinical practice guideline recommendation9 for 12 months of dual antiplatelet therapy after placement of a drug-eluting stent in patients who are not at high risk of bleeding. However, they agreed that a large randomized trial looking specifically at appropriate duration of dual antiplatelet therapy is needed.

Premature Thienopyridine Discontinuation and Stent Thrombosis

The premature discontinuation of thienopyridine therapy is associated with a marked increase in the risk of stent thrombosis and is the leading independent predictor for stent thrombosis in multivariate analyses. Although the number of actual stent thromboses reported in individual studies is modest, the findings are noteworthy.

In a large observational cohort study of patients treated with DES, stent thrombosis occurred in a striking 29% of patients in whom antiplatelet therapy was discontinued prematurely.9 This discontinuation of antiplatelet therapy was associated with a hazard ratio of 161 (95% confidence interval 26 to 998) for the occurrence of subacute stent thrombosis and a hazard ratio of 57 (95% confidence interval 15 to 220) for the occurrence of late (>30 days) stent thrombosis.

In a single-site study of 652 patients treated with sirolimus DES, premature discontinuation of clopidogrel was associated with an ≈30-fold greater risk of stent thrombosis, with >25% of patients who discontinued clopidogrel therapy within the first month suffering stent thrombosis.17 Park et al13 reported on 1911 patients who discontinued clopidogrel therapy within the first 6 months, late stent thrombosis with an asymptotic (hazard ratio 2.6% versus 1.3%) and death or nonfatal MI (4.9% versus 3.0%).

Similarly, Eisenstein et al21 reported an observational study in the PREMIER (Prospective Registry Evaluating Myocardial Infarction: Events and Recovery) registry of 500 patients with acute MI treated with DES. The mortality rate over the next 11 months of those who stopped thienopyridine therapy was 7.5% compared with 0.7% in those who had not stopped therapy (hazard ratio 9.0, P<0.0001). Although the rates of stent thrombosis were not reported, it is reasonable to presume that many of the deaths were related to coronary artery disease.

Several reports have specifically described incidents of stent thrombosis that occurred after the discontinuation of antiplatelet therapy for noncardiac surgery within 90 days of bare-metal stent implantation, 6 of the 7 patients in whom thienopyridine therapy was discontinued died “in a manner suggestive of stent thrombosis.”26

Factors Related to Premature Cessation of Thienopyridine Therapy

Premature cessation of thienopyridine may occur for several different reasons. The cost of clopidogrel (approximately $4 daily) has been cited as one reason patients discontinue (or do not renew) their therapy.22 It is unclear whether the introduction of modestly lower-cost generic clopidogrel will significantly affect this issue. In an analysis from the PREMIER registry,19 factors identified with premature discontinuation of thienopyridine therapy included older age, not having completed high school, not being married, not receiving discharge instructions for medication use, not being referred for cardiac rehabilitation, greater likelihood of having preexistent cardiovascular disease or anemia, and not seeking health care because of cost. The study authors concluded that “additional patient education about the rationale for and importance of continuing thienopyridine treatment may be needed—particularly for patients with less formal education.”

Antiplatelet therapy may be stopped at the instruction of physicians, dentists, and other healthcare providers who are to perform an invasive or surgical procedure on the patient because of misguided concerns about excessive procedure-related bleeding. Unfortunately, many patients are routinely instructed to stop “blood thinners” before such procedures without a thorough evaluation of the rationale for such therapy and without distinction between warfarin and antiplatelet agents. Many of these procedures (eg, minor surgery, teeth cleaning, and tooth extraction) can likely be performed at no or only minor risk of bleeding or could be delayed until the prescribed antiplatelet regimen is completed. Although there is a longstanding concern on the part of dental practitioners about the possibility of prolonged bleeding during and after invasive dental procedures on patients taking antiplatelet drugs, a recent prospective study of single tooth extractions on patients randomized to aspirin versus a placebo failed to show a statistically significant difference in postoperative bleeding.29 Although there are no prospective studies of invasive dental procedures on patients taking a thienopyridine alone or in combination with aspirin, there are also no well-documented cases of clinically significant bleeding after dental procedures, including multiple dental extractions. Given the relative ease with which the incidence and severity of oral bleeding can be reduced with local measures during surgery (eg, absorbable gelatin sponge and sutures) and the unlikely occurrence of bleeding once an initial clot has formed, there is little or no indication to interrupt antiplatelet drugs for dental procedures.30

The likelihood of increased bleeding and/or an increased requirement for blood transfusion in patients undergoing major noncardiac surgery can be inferred from reports of increased bleeding when...
cardiac surgery (including off-pump coronary bypass grafting) is undertaken in patients taking a thienopyridine drug. Independent documentation of the scope of this risk of increased bleeding during noncardiac surgery, however, is not available. If one must discontinue the thienopyridine drug before major surgery to reduce the risk of excessive bleeding, consideration should be given to continuing aspirin for its antiplatelet action to mitigate the risk of late stent thrombosis and to restarting the thienopyridine as soon as possible. Although some have attempted “bridging” stent patients with antithrombin agents, there is no evidence of a benefit of warfarin (Table 1) or other antithrombins, and there is an increased risk of bleeding.31 Similarly, there are no data to support the use of “bridging” glycoprotein IIb/IIIa agents.

**Summary and Recommendations**

Thienopyridine therapy in combination with aspirin has become the mainstay antiplatelet treatment strategy for the prevention of stent thrombosis. Premature discontinuation of antiplatelet therapy markedly increases the risk of stent thrombosis, a catastrophic event that frequently leads to MI and/or death. Factors contributing to premature cessation of thienopyridine therapy include drug cost, physician/dentist instructions to patients to discontinue therapy before procedures, and inadequate patient education and understanding about the importance of continuing therapy.

To eliminate premature discontinuation of thienopyridine therapy, this advisory group gives the following recommendations.

1. Before implantation of a stent, the physician should discuss the need for dual antiplatelet therapy. In patients not expected to comply with 12 months of thienopyridine therapy, whether for economic or other reasons, strong consideration should be given to avoiding a DES.

2. In patients who are undergoing preparation for percutaneous coronary intervention and are likely to require invasive or surgical procedures within the next 12 months, consideration should be given to implantation of a bare-metal stent or performance of balloon angioplasty with provisional stent implantation instead of the routine use of a DES.

3. A greater effort by healthcare professionals must be made before patient discharge to ensure patients are properly and thoroughly educated about the reasons they are prescribed thienopyridines and the significant risks associated with prematurely discontinuing such therapy.

4. Patients should be specifically instructed before hospital discharge to contact their treating cardiologist before stopping any antiplatelet therapy, even if instructed to stop such therapy by another healthcare provider.

5. Healthcare providers who perform invasive or surgical procedures and are concerned about peri procedural and post procedural bleeding must be made aware of the potentially catastrophic risks of premature discontinuation of thienopyridine therapy. Such professionals who perform these procedures should contact the patient’s cardiologist if issues regarding the patient’s antiplatelet therapy are unclear, to discuss optimal patient management strategy.

6. Elective procedures for which there is significant risk of perioperative or postoperative bleeding should be deferred until patients have completed an appropriate course of thienopyridine therapy (12 months after DES implantation if they are not at high risk of bleeding and a minimum of 1 month for bare-metal stent implantation).

7. For patients treated with DES who are to undergo subsequent procedures that mandate discontinuation of thienopyridine therapy, aspirin should be continued if at all possible and the thienopyridine restarted as soon as possible after the procedure because of concerns about late-stent thrombosis.

8. The healthcare industry, insurers, the US Congress, and the pharmaceutical industry should ensure that issues such as drug cost do not cause patients to prematurely discontinue thienopyridine therapy and to thus incur catastrophic cardiovascular complications.
