Yancy CW, et al
Heart Failure Focused Update on Pharmacological Therapy

Preamble

Incorporation of new study results, medications, or devices that merit modification of existing clinical practice guideline recommendations, or the addition of new recommendations, is critical to ensuring that guidelines reflect current knowledge, available treatment options, and optimum medical care. To keep pace with evolving evidence, the American College of Cardiology (ACC)/American Heart Association (AHA) Task Force on Clinical Practice Guidelines (“Task Force”) has issued this focused update to reassess guideline recommendations on the basis of recently published study data. This update has been subject to rigorous, multilevel review and approval, similar to the full guidelines. For specific focused update criteria and additional methodological details, please see the ACC/AHA guideline methodology manual (1).

Modernization—Processes have evolved over time in response to published reports from the Institute of Medicine (2, 3) and ACC/AHA mandates (4-7), leading to adoption of a “knowledge byte” format. This process entails delineation of a recommendation addressing a specific clinical question, followed by concise text (ideally <250 words) and hyperlinked to supportive evidence. This approach better accommodates time constraints on busy clinicians, facilitates easier access to recommendations via electronic search engines and other evolving technology, and supports the evolution of guidelines as “living documents” that can be dynamically updated as needed.

Guideline-Directed Evaluation and Management—The term guideline-directed evaluation and management (GDEM) refers to care defined mainly by ACC/AHA Class I recommendations. For these and all recommended drug treatment regimens, the reader should confirm dosage with product insert material and carefully evaluate for contraindications and interactions. Recommendations are limited to treatments, drugs, and devices approved for clinical use in the United States.

Class of Recommendation and Level of Evidence—The Class of Recommendation (COR) and Level of Evidence (LOE) are derived independently of each other according to established criteria. The COR indicates the strength of recommendation, encompassing the estimated magnitude and certainty of benefit of a clinical action in proportion to risk. The LOE rates the quality of scientific evidence supporting the intervention on the basis of the type, quantity, and consistency of data from clinical trials and other sources (Table 1). Recommendations in this focused update reflect the new 2015 COR/LOE system, in which LOE B and C are subcategorized for the purpose of increased granularity (1, 5, 8).

Relationships With Industry and Other Entities—The ACC and AHA exclusively sponsor the work of guideline writing committees without commercial support, and members volunteer time for this activity. Selected organizations and professional societies with related interests and expertise are invited to participate as partners or collaborators. The Task Force makes every effort to avoid actual, potential, or perceived conflicts of interest that might arise through relationships with industry or other entities (RWI). All writing committee members and reviewers are required to fully disclose current industry relationships or personal interests, beginning 12 months before initiation of the writing effort. Management of RWI involves selecting a balanced writing committee and requires that both the chair and a majority of writing committee members have no relevant RWI (see Appendix 1 for the definition of relevance). Members are restricted with regard to writing or voting on sections to which RWI apply. Members of the writing
committee who recused themselves from voting are indicated and specific section recusals are noted in Appendix 1. In addition, for transparency, members’ comprehensive disclosure information is available as an Online Supplement (http://circ.ahajournals.org/lookup/suppl/doi:10.1161/CIR.0000000000000435/-/DC1), and reviewers’ RWI disclosures are included in Appendix 2. Comprehensive disclosure information for the Task Force is also available at http://www.acc.org/about-acc/leadership/guidelines-and-documents-task-forces.aspx The Task Force strives to avoid bias by selecting experts from a broad array of backgrounds representing different geographic regions, genders, ethnicities, intellectual perspectives, and scopes of clinical activities.

Intended Use—Guidelines provide recommendations applicable to patients with or at risk of developing cardiovascular disease. The focus is on medical practice in the United States, but guidelines developed in collaboration with other organizations may have a broader target. Although guidelines may be used to inform regulatory or payer decisions, the intent is to improve quality of care and align with patients’ interests. The guidelines are reviewed annually by the Task Force and are official policy of the ACC and AHA. Each guideline is considered current unless and until it is updated, revised, or superseded by a published addendum.

Related Issues—For additional information pertaining to the methodology for grading evidence, assessment of benefit and harm, shared decision making between the patient and clinician, structure of evidence tables and summaries, standardized terminology for articulating recommendations, organizational involvement, peer review, and policies regarding periodic assessment and updating of guideline documents, we encourage readers to consult the ACC/AHA guideline methodology manual (1).

Jonathan L. Halperin, MD, FACC, FAHA
Chair, ACC/AHA Task Force on Clinical Practice Guidelines
Introduction

The ACC, the AHA, and the Heart Failure Society of America (HFSA) recognize that the introduction of effective new therapies that potentially affect a large number of patients presents both opportunities and challenges. The introduction of an angiotensin receptor–neprilysin inhibitor (ARNI) (valsartan/sacubitril) and a sinoatrial node modulator (ivabradine), when applied judiciously, complements established pharmacological and device-based therapies and represents a milestone in the evolution of care for patients with heart failure (HF). Accordingly, the writing committees of the “2016 ACC/AHA/HFSA Focused Update on New Pharmacological Therapy for Heart Failure” and the “2016 ESC Guideline on the Diagnosis and Treatment of Acute and Chronic Heart Failure” concurrently developed recommendations for the incorporation of these therapies into clinical practice. Working independently, each writing committee surveyed the evidence, arrived at similar conclusions, and constructed similar, but not identical, recommendations. Given the concordance, the respective organizations simultaneously issued aligned recommendations on the use of these new treatments to minimize confusion and improve the care of patients with HF.

Members of the ACC/AHA/HFSA writing committee without relevant RWI voted on the final recommendations. These were subjected to external peer review by 25 official, organizational, and content reviewers before approval by the Task Force and the leadership of the ACC, AHA, and HFSA, as well as endorsement by the International Society for Heart and Lung Transplantation. The statements issued by the European Society of Cardiology writing committee went through a similarly rigorous process of external review before endorsement by the societal leadership.

No single clinical trial answers all pertinent questions, nor can trial results be perfectly replicated in clinical practice. Several critical questions remain unanswered, and further experience in both ongoing trials and clinical therapeutics may require modification of these initial recommendations. On the basis of the currently available evidence, however, the recommendations that follow reflect our assessment of how best to proceed today.
### Table 1. Applying Class of Recommendation and Level of Evidence to Clinical Strategies, Interventions, Treatments, or Diagnostic Testing in Patient Care* (Updated August 2015)

<table>
<thead>

</tr>
</tbody>
</table>

COR and LOE are determined independently (any COR may be paired with any LOE).

A recommendation with LOE C does not imply that the recommendation is weak. Many important clinical questions addressed in guidelines do not lend themselves to clinical trials. Although RCTs are unavailable, there may be a very clear clinical consensus that a particular test or therapy is useful or effective.

* The outcome or result of the intervention should be specified (an improved clinical outcome or increased diagnostic accuracy or incremental prognostic information).

† For comparative-effectiveness recommendations (COR I and IIa; LOE A and B only), studies that support the use of comparator verbs should involve direct comparisons of the treatments or strategies being evaluated.

‡ The method of assessing quality is evolving, including the application of standardized, widely used, and preferably validated evidence grading tools; and for systematic reviews, the incorporation of an Evidence Review Committee.

COR indicates Class of Recommendation; EO, expert opinion; LD, limited data; LOE, Level of Evidence; NR, nonrandomized; R, randomized; and RCT, randomized controlled trial.
7.3. Stage C

7.3.2. Pharmacological Treatment for Stage C HF With Reduced Ejection Fraction: Recommendations

7.3.2.10. Renin-Angiotensin System Inhibition With Angiotensin-Converting Enzyme Inhibitor or Angiotensin Receptor Blocker or ARNI: Recommendations

See the Online Data Supplement (http://circ.ahajournals.org/lookup/suppl/doi:10.1161/CIR.0000000000000435/-/DC2) for evidence supporting these recommendations.

<table>

<tr>
<td>I</td>
<td>ACE: A</td>
<td>The clinical strategy of inhibition of the renin-angiotensin system with ACE inhibitors (Level of Evidence: A) (9-14), OR ARBs (Level of Evidence: A) (15-18), OR ARNI (Level of Evidence: B-R) (19) in conjunction with evidence-based beta blockers (20-22), and aldosterone antagonists in selected patients (23, 24), is recommended for patients with chronic HFrEF to reduce morbidity and mortality.</td>
</tr>
<tr>
<td></td>
<td>ARB: A</td>
<td>Angiotensin-converting enzyme (ACE) inhibitors reduce morbidity and mortality in heart failure with reduced ejection fraction (HFrEF). Randomized controlled trials (RCTs) clearly establish the benefits of ACE inhibition in patients with mild, moderate, or severe symptoms of HF and in patients with or without coronary artery disease (9-14). ACE inhibitors can produce angioedema and should be given with caution to patients with low systemic blood pressures, renal insufficiency, or elevated serum potassium. ACE inhibitors also inhibit kininase and increase levels of bradykinin, which can induce cough but also may contribute to their beneficial effect through vasodilation. Angiotensin receptor blockers (ARBs) were developed with the rationale that angiotensin II production continues in the presence of ACE inhibition, driven through alternative enzyme pathways. ARBs do not inhibit kininase and are associated with a much lower incidence of cough and angioedema than ACE inhibitors; but like ACE inhibitors, ARBs should be given with caution to patients with low systemic blood pressure, renal insufficiency, or elevated serum potassium. Long-term therapy with ARBs produces hemodynamic, neurohormonal, and clinical effects consistent with those expected after interference with the renin-angiotensin system and have been shown in RCTs (15-18) to reduce morbidity and mortality, especially in ACE inhibitor-intolerant patients. In ARNI, an ARB is combined with an inhibitor of neprilysin, an enzyme that degrades natriuretic peptides, bradykinin, adrenomedullin, and other vasoactive peptides. In an RCT that compared the first approved ARNI,</td>
</tr>
<tr>
<td></td>
<td>ARNI: B-R</td>

</tr>
</tbody>
</table>
valsartan/sacubitril, with enalapril in symptomatic patients with HFrEF tolerating an adequate dose of either ACE inhibitor or ARB, the ARNI reduced the composite endpoint of cardiovascular death or HF hospitalization significantly, by 20% (19). The benefit was seen to a similar extent for both death and HF hospitalization and was consistent across subgroups. The use of ARNI is associated with the risk of hypotension and renal insufficiency and may lead to angioedema, as well.

<table>
<thead>
<tr>
<th></th>
<th>ACE: A</th>
<th>The use of ACE inhibitors is beneficial for patients with prior or current symptoms of chronic HFrEF to reduce morbidity and mortality (9-14, 25).</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>ARB: A</td>
<td>The use of ARBs to reduce morbidity and mortality is recommended in patients with prior or current symptoms of chronic HFrEF who are intolerant to ACE inhibitors because of cough or angioedema (15-18, 27, 28).</td>
</tr>
</tbody>
</table>

ACE inhibitors have been shown in large RCTs to reduce morbidity and mortality in patients with HFrEF with mild, moderate, or severe symptoms of HF, with or without coronary artery disease (9-14). Data suggest that there are no differences among available ACE inhibitors in their effects on symptoms or survival (25). ACE inhibitors should be started at low doses and titrated upward to doses shown to reduce the risk of cardiovascular events in clinical trials. ACE inhibitors can produce angioedema and should be given with caution to patients with low systemic blood pressures, renal insufficiency, or elevated serum potassium (>5.0 mEq/L). Angioedema occurs in <1% of patients who take an ACE inhibitor, but it occurs more frequently in blacks and women (26). Patients should not be given ACE inhibitors if they are pregnant or plan to become pregnant. ACE inhibitors also inhibit kininase and increase levels of bradykinin, which can induce cough in up to 20% of patients but also may contribute to beneficial vasodilation. If maximal doses are not tolerated, intermediate doses should be tried; abrupt withdrawal of ACE inhibition can lead to clinical deterioration and should be avoided.

Although the use of an ARNI in lieu of an ACE inhibitor for HFrEF has been found to be superior, for those patients for whom ARNI is not appropriate, continued use of an ACE inhibitor for all classes of HFrEF remains strongly advised.

ARBs have been shown to reduce mortality and HF hospitalizations in patients with HFrEF in large RCTs (15-18). Long-term therapy with ARBs in patients with HFrEF produces hemodynamic, neurohormonal, and clinical effects consistent with those expected after interference with the renin-angiotensin system (27, 28). Unlike ACE inhibitors, ARBs do not inhibit kininase and are associated with a much lower incidence of cough and angioedema, although kininase inhibition by ACE inhibitors may produce beneficial vasodilatory effects.

Patients intolerant to ACE inhibitors because of cough or angioedema should be started on ARBs; patients already tolerating ARBs for other

See Online Data Supplements 2 and 19.
indications may be continued on ARBs if they subsequently develop HF. ARBs should be started at low doses and titrated upward, with an attempt to use doses shown to reduce the risk of cardiovascular events in clinical trials. ARBs should be given with caution to patients with low systemic blood pressure, renal insufficiency, or elevated serum potassium (>5.0 mEq/L). Although ARBs are alternatives for patients with ACE inhibitor-induced angioedema, caution is advised because some patients have also developed angioedema with ARBs.

Head-to-head comparisons of an ARB versus ARNI for HF do not exist. For those patients for whom an ACE inhibitor or ARNI is inappropriate, use of an ARB remains advised.

<table>
<thead>
<tr>
<th>Indication</th>
<th>ARNI: B-R</th>
</tr>
</thead>
<tbody>
<tr>
<td>In patients with chronic symptomatic HFrEF NYHA class II or III who tolerate an ACE inhibitor or ARB, replacement by an ARNI is recommended to further reduce morbidity and mortality (19).</td>
<td></td>
</tr>
<tr>
<td>Benefits of ACE inhibitors with regard to decreasing HF progression, hospitalizations, and mortality rate have been shown consistently for patients across the clinical spectrum, from asymptomatic to severely symptomatic HF. Similar benefits have been shown for ARBs in populations with mild-to-moderate HF who are unable to tolerate ACE inhibitors. In patients with mild-to-moderate HF (characterized by either 1) mildly elevated natriuretic peptide levels, BNP [B-type natriuretic peptide] &gt;150 pg/mL or NT-proBNP [N-terminal pro-B-type natriuretic peptide] ≥600 pg/mL; or 2) BNP ≥100 pg/mL or NT-proBNP ≥400 pg/mL with a prior hospitalization in the preceding 12 months) who were able to tolerate both a target dose of enalapril (10 mg twice daily) and then subsequently an ARNI (valsartan/sacubitril; 200 mg twice daily, with the ARB component equivalent to valsartan 160 mg), hospitalizations and mortality were significantly decreased with the valsartan/sacubitril compound compared with enalapril. The target dose of the ACE inhibitor was consistent with that known to improve outcomes in previous landmark clinical trials (10). This ARNI has recently been approved for patients with symptomatic HFrEF and is intended to be substituted for ACE inhibitors or ARBs. HF effects and potential off-target effects may be complex with inhibition of the neprilysin enzyme, which has multiple biological targets. Use of an ARNI is associated with hypotension and a low-frequency incidence of angioedema. To facilitate initiation and titration, the approved ARNI is available in 3 doses that include a dose that was not tested in the HF trial; the target dose used in the trial was 97/103 mg twice daily (29). Clinical experience will provide further information about the optimal titration and tolerability of ARNI, particularly with regard to blood pressure, adjustment of concomitant HF medications, and the rare complication of angioedema (30).</td>
<td></td>
</tr>
<tr>
<td>ARNI should not be administered concomitantly with ACE inhibitors or within 36 hours of the last dose of an ACE inhibitor (31, 32).</td>
<td></td>
</tr>
</tbody>
</table>

See Online Data Supplements 1 and 18.

See Online Data Supplement 3.
Omapatrilat, was studied in both hypertension and HF, but its development was terminated because of an unacceptable incidence of angioedema (31, 32) and associated significant morbidity. This adverse effect was thought to occur because both ACE and neprilysin break down bradykinin, which directly or indirectly can cause angioedema (32, 33). An ARNI should not be administered within 36 hours of switching from or to an ACE inhibitor.

**III: Harm**

<table>
<thead>
<tr>
<th>C-EO</th>
<th>ARNI should not be administered to patients with a history of angioedema.</th>
</tr>
</thead>
</table>

Omapatrilat, a neprilysin inhibitor (as well as an ACE inhibitor and aminopeptidase P inhibitor), was associated with a higher frequency of angioedema than that seen with enalapril in an RCT of patients with HFrEF (31). In a very large RCT of hypertensive patients, omapatrilat was associated with a 3-fold increased risk of angioedema as compared with enalapril (32). Blacks and smokers were particularly at risk. The high incidence of angioedema ultimately led to cessation of the clinical development of omapatrilat (34, 35). In light of these observations, angioedema was an exclusion criterion in the first large trial assessing ARNI therapy in patients with hypertension (36) and then in the large trial that demonstrated clinical benefit of ARNI therapy in HFrEF (19). ARNI therapy should not be administered in patients with a history of angioedema because of the concern that it will increase the risk of a recurrence of angioedema.

### 7.3.2.11. Ivabradine: Recommendation

See the Online Data Supplement (http://circ.ahajournals.org/lookup/suppl/doi:10.1161/CIR.0000000000000435/-/DC2) for evidence supporting this recommendation.

<table>
<thead>
<tr>
<th>COR</th>
<th>LOE</th>
<th>Recommendation</th>
</tr>
</thead>
<tbody>
<tr>
<td>IIa</td>
<td>B-R</td>
<td>Ivabradine can be beneficial to reduce HF hospitalization for patients with symptomatic (NYHA class II-III) stable chronic HFrEF (LVEF ≤35%) who are receiving GDEM, including a beta blocker at maximum tolerated dose, and who are in sinus rhythm with a heart rate of 70 bpm or greater at rest (37-40).</td>
</tr>
</tbody>
</table>

Ivabradine is a new therapeutic agent that selectively inhibits the I_f current in the sinoatrial node, providing heart rate reduction. One RCT demonstrated the efficacy of ivabradine in reducing the composite endpoint of cardiovascular death or HF hospitalization (38). The benefit of ivabradine was driven by a reduction in HF hospitalization. The study included patients with HFrEF (NYHA class II-IV, albeit with only a modest representation of NYHA class IV HF) and left ventricular ejection fraction (LVEF) ≤35%, in sinus rhythm with a resting heart rate of ≥70 beats per minute. Patients enrolled included a small number with paroxysmal atrial fibrillation (<40% of the time) but otherwise in
Yancy CW, et al
Heart Failure Focused Update on Pharmacological Therapy

sinus rhythm and a small number experiencing ventricular pacing but with a predominant sinus rhythm. Those with a myocardial infarction within the preceding 2 months were excluded. Patients enrolled had been hospitalized for HF in the preceding 12 months and were on stable GDEM for 4 weeks before initiation of ivabradine therapy. The target of ivabradine is heart rate slowing (the presumed benefit of action), but only 25% of patients studied were on optimal doses of beta-blocker therapy (20-22, 38). Given the well-proven mortality benefits of beta-blocker therapy, it is important to initiate and up titrate these agents to target doses, as tolerated, before assessing the resting heart rate for consideration of ivabradine initiation (38).

The remainder of the “2016 ACC/AHA/HFSA Focused Update on the Management of Heart Failure: An Update of the 2013 ACCF/AHA Guideline for the Management of Heart Failure” will be forthcoming.

This table represents the relationships of committee members with industry and other entities that were determined to be relevant to this document. These relationships were reviewed and updated in conjunction with all meetings and/or conference calls of the writing committee during the document development process. The table does not necessarily reflect relationships with industry at the time of publication. A person is deemed to have a significant interest in a business if the interest represents ownership of ≥5% of the voting stock or share of the business entity, or ownership of ≥$5,000 of the fair market value of the business entity, or if funds received by the person from the business entity exceed 5% of the person’s gross income for the previous year. Relationships that exist with no financial benefit are also included for the purpose of transparency. Relationships in this table are modest unless otherwise noted.

According to the ACC/AHA, a person has a relevant relationship if:

a) The relationship or interest relates to the same or similar subject matter, intellectual property or asset, topic, or issue addressed in the document; or b) the company/entity (with whom the relationship exists) makes a drug, drug class, or device addressed in the document, or makes a competing drug or device addressed in the document; or c) the person or a member of the person’s household has a reasonable potential for financial, professional, or other personal gain or loss as a result of the issues/content addressed in the document.

*Writing committee members are required to recuse themselves from voting on sections to which their specific relationships with industry and other entities may apply.
†Significant relationship.

ACC indicates American College of Cardiology; AHA, American Heart Association; DCRI, Duke Clinical Research Institute; DSMB, data safety monitoring board; HFSA, Heart Failure Society of America; UCLA, University of California, Los Angeles; and VA, Veterans Affairs.

This table represents the relationships of reviewers with industry and other entities that were disclosed at the time of peer review, including those not deemed to be relevant to this document. The table does not necessarily reflect relationships with industry at the time of publication. A person is deemed to have a significant interest in a business if the interest represents ownership of ≥5% of the voting stock or share of the business entity, or ownership of ≥$5,000 of the fair market value of the business entity, or if funds received by the person from the business entity exceed 5% of the person’s gross income for the previous year. A relationship is considered to be modest if it is less than significant under the preceding definition. Relationships that exist with no financial benefit are also included for the purpose of transparency. Relationships in this table are modest unless otherwise noted. Names are listed in alphabetical order within each category of review. American College of Physicians did not provide a peer reviewer for this document.

---

*Significant relationship.
†No financial benefit.

AAFP indicates American Academy of Family Physicians; ACC, American College of Cardiology; AHA, American Heart Association; ASA, American Stroke Association; CHEST, American College of Chest Physicians; CIHR, Canadian Institutes of Health Research; DSMB, data safety monitoring board; FH, familial hypercholesterolemia; GWTG, Get With The Guidelines; HFSA, Heart Failure Society of America; ISHLT, International Society for Heart and Lung Transplantation; NIH, National Institutes of Health; NHLBI, National Heart, Lung, and Blood Institute; NQF, National Quality Forum; PCORI, Patient-Centered Outcomes Research Institute; SCAI, Society for Cardiac Angiography and Interventions; SUNY, State University of New York; UT, University of Texas; and VA, Veterans Affairs.

This table represents all relationships of committee members with industry and other entities that were reported by authors, including those not deemed to be relevant to this document, at the time this document was under development. The table does not necessarily reflect relationships with industry at the time of publication. A person is deemed to have a significant interest in a business if the interest represents ownership of ≥5% of the voting stock or share of the business entity, or ownership of ≥$5,000 of the fair market value of the business entity; or if funds received by the person from the business entity exceed 5% of the person’s gross income for the previous year. Relationships that exist with no financial benefit are also included for the purpose of transparency. Relationships in this table are modest unless otherwise noted. Please refer to [http://www.acc.org/guidelines/about-guidelines-and-clinical-documents/relationships-with-industry-policy](http://www.acc.org/guidelines/about-guidelines-and-clinical-documents/relationships-with-industry-policy) for definitions of disclosure categories or additional information about the ACC/AHA Disclosure Policy for Writing Committees.

*Significant relationship.  
†No financial benefit.

Data Supplement 1. RCTs Comparing ARNI (Section 7.3.2.10)

| Study Acronym; Author; Year Published | Aim of Study; Study Type; Study Size (N) | Patient Population | Study Intervention | Endpoint Results (Absolute Event Rates, P values; OR or RR; & 95% CI) | Relevant 2° Endpoint (if any); Study Limitations; Adverse Events |
|-------------------------------------|-------------------------------------|--------------------|--------------------|----------------------------------------------------------------|----------------------------------------------------------------
| PARAMOUNT Solomon et al. 2012 (1) 22932717 | Aim: To address safety and efficacy of LCZ696 (ARNI) in pts with HFrEF | Inclusion criteria: Pts ≥40 y of age, LVEF ≥45%, NYHA class II-III HF, NT-pro BNP >400 pg/mL. | Intervention: LCZ696 (149) target dose 200 mg BID achieved in 81% | 1° endpoint: • Change from BL at 12 wk for NT-proBNP • Results: Reduction in LCZ696 group vs. valsartan (ratio of change from BL: 0.77, 95% CI: 0.64–0.92; p=0.005) 1° Safety endpoint: • LCZ-696 well tolerated. • Serious adverse events: |
|                                       | Study type: RCT | Exclusion criteria: Right HF due to pulmonary disease, dyspnea due to noncardiac causes, valvular/myocardial disease, CAD or CVD needing revascularization within 3 mo of screening. | Comparator:Valsartan (152) target dose 160 mg BID achieved in 78% | |
|                                       | Size: 308 | | | | • No difference in change in NT-proBNP from BL at 36 wk • BP reduced in the LCZ696 group vs. valsartan at 12 wk (p=0.001 for SBP and p=0.09 for DBP) • Change in BP correlated poorly with the change in pro-BNP • No difference in improvement in NYHA class at 12 wk (p=0.11) and 36 wk (p=0.05). • No difference in KCCQ scores • Trial not powered to ascertain clinical
### PARADIGM-HF

**McMurray et al. 2014**

| **Aim:** | To compare survival rates with the use of LCZ696 with enalapril in HF |
| **Study type:** | RCT |
| **Size:** | 8,442 |

#### Inclusion criteria:
- ≥18 y of age, NYHA class II, III, IV; EF ≤35%, BNP of at least 150 pg/mL, hospitalized for HF ≤12 mo (≥BNP100 pg/mL), on ACE inhibitors or ARBs ≥4 wk before screening, required to take stable dose of beta blockers and an ACE inhibitor (or ARB) equal to 10mg of enalapril. Prior to randomization pts were required to complete 2 wk each of enalapril 10 mg BID and LCZ 100 BID. |

#### Exclusion criteria:
- Symptomatic hypotension, SBP <95 mm Hg, eGFR <30 mL/min/1.73m² of body surface area, serum K level >5.2 mmol/L, angioedema history, unacceptable side effects of ACE inhibitors or ARBs |

#### Intervention:
- LCZ696 (4,187) target dose 200 mg BID (mean 375±71 mg daily) |

#### Comparator:
- Enalapril (4,212) target 10 mg BID (mean 18.9±3.4 mg daily) |

#### 1° endpoint:
- Composite of death (CV causes) or a first hospitalization for HF |

#### Results:
- Composite less in LCZ696 group vs. enalapril, 914 (21.8%) vs. 1,117, (26.5%) HR: 0.80 (95% CI: 0.73–0.87; p<0.001) |
- Less CV death in LCZ696 arm (558 vs. 693) HR: 0.8 (95% CI: 0.71–0.89; p<0.001) |
- Less HF hospitalizations in LCZ696 arm (537 vs. 658) HR: 0.8 (95% CI: 0.71–0.89; p<0.001) |
- Less death from any cause in LCZ696 arm (711 vs. 835), HR: 0.84 (95% CI: 0.76–0.93; p<0.001) |
- The change from baseline to 8 mo in the score on the KCCQ in LCZ696 arm (2.99 points reduction vs. 4.63 points), HR: 1.64 (95% CI: 0.63–2.65; p=0.001) |
- No difference in new onset of AF (84 vs. 83; p=0.84) |
- No difference in protocol defined decline in renal function, HR: 0.86 (95% CI: 0.65–1.13; p=0.28). |
- More symptomatic hypotension (14% vs. 9.2%; p<0.001) |
- No difference in angioedema, 19 vs.10 (p=0.13) |

AF indicates atrial fibrillation; ARNI/LCZ696, angiotensin receptor-neprilysin inhibitor; ACE, angiotensin-converting enzyme; ARB, angiotensin-receptor blocker; BL, baseline; BID; twice a day; BNP, plasma B-type natriuretic peptide; BP, blood pressure; CAD, coronary artery disease; CI, confidence interval; CVD, cardiovascular disease; CV, cardiovascular; EF, ejection fraction; eGFR, estimated glomerular filtration rate; HF, heart failure; HFpEF, heart failure with preserved ejection fraction; HR, hazard ratio; KCCQ, Kansas City Cardiomyopathy Questionnaire; LVEF, left ventricular ejection fraction; N/A, not available; NT-proBNP, N-terminal pro-B-type natriuretic peptide; NYHA, New York Heart Association; PARAMOUNT, Prospective Comparison of ARNI With ARB on Management of Heart Failure With Preserved Ejection Fraction; PARADIGM-HF, Prospective Comparison of ARNI With ACE to Determine Impact on Global Mortality and Morbidity in Heart Failure; pts, patients; RCT, randomized controlled trial; and SBP, systolic blood pressure.

Search Terms and Date: 3 trials identified by chairs in December 2015.
### Data Supplement 2. RCTs Comparing RAAS Inhibition (Section 7.3.2.3)

<td><strong>Inclusion Criteria:</strong> ACE-intolerant pts with CAD, PVD, previous stroke, or high-risk DM with end-organ damage</td>
<td><strong>Intervention:</strong> Run in, then randomization to telmisartan titrated to 80 mg as tolerated (2,954)</td>
<td><strong>1° endpoint:</strong> • Composite of CV death, MI, stroke, or HF hospitalization at 5 y</td>
<td><strong>No difference in 2° outcomes; ARB was safe in this pt population - no angioedema</strong></td>
</tr>
<tr>
<td>SUPPORT Sakata et al. 2015</td>
<td><strong>Aim:</strong> Discover whether addition of ARB to ACE and beta blockers in pts with chronic HF will improve clinical outcomes</td>
<td><strong>Inclusion Criteria:</strong> Pts 20–79 y of age with hypertension, NYHA class II-IV, stable on ACE ± beta blockers</td>
<td><strong>Intervention:</strong> Randomization to olmesartan (578) titrated up to 40 mg as tolerated (578) (mean dose achieved at 5 y, 17.9 mg/d)</td>
<td><strong>1° endpoint:</strong> • Composite of all-cause death, MI, stroke, or HF hospitalization at 4.4 y</td>
<td><strong>Pts on triple therapy with ACE/ARB/Beta blocker had more of 1° composite outcome, 38.1 vs. 28.2%, HR: 1.47 (95% CI: 1.11–1.95; p=0.006); all-cause death, 19.4 vs. 13.5%, HR: 1.50 (95% CI: 1.01–2.23; p=0.046); and renal dysfunction (21.1 vs. 12.5%, HR: 1.85 (95% CI: 1.24–2.76; p=0.003).</strong></td>
</tr>
</tbody>
</table>

© 2016 American College of Cardiology Foundation and American Heart Association, Inc.
**EMPHASIS subgroup analysis**

*Eschalier et al. 2013 (6) 23810881*

**Aim:** Investigate the safety and efficacy of eplerenone in pts at high risk for hyperkalemia

**Study Type:** Prespecified subgroup analysis of RCT

**Size:** 2,737

**Inclusion Criteria:** Pts enrolled in EMPHASIS at high risk for hyperkalemia of worsening renal function (>75 y, DM, eGFR <60, or SBP <123)

**Exclusion Criteria:** eGFR<30

**Intervention:** Randomization to eplerenone

**Comparator:** Placebo

**1° endpoint:**
- **Efficacy:** Hospitalization for HF or worsening renal failure. **Safety:** K >5.5, >6.0, <3.5, hospitalization for significant hyperkalemia, hospitalization for worsening renal function

**Results:** Efficacy: reduced composite endpoint. Safety: increased risk of K+ >5.5 mmol/L, hospitalization for hyperkalemia or discontinuation of study medication due to adverse events. No differences from the main trial results in the high-risk subgroups. K >5.5 was increased in the whole cohort and the subgroups, but K >6.0, clinically significant hyperkalemia, and change in eGFR were not substantially higher.

**RALES**

*Pitt et al. 1999 (7) 10471456*

**Aim:** To investigate the effect of spironolactone on mortality and morbidity in pts with severe HF.

**Study Type:** RCT

**Size:** 1,663

**Inclusion Criteria:** NYHA class III, IV; HF ≤6 mo, Left EF ≤35%, On ACE inhibitors, loop diuretic. Digitalis and vasodilators allowed.

**Exclusion Criteria:** 1° operable VHD (other than mitral or tricuspid), ACHD, unstable angina, 1° heaptic failure, active cancer, life threatening disease, heart transplant, serum Cr ≥2.5 mg/dL, serum K ≥5.0 mmol/L

**Intervention:** Spironolactone 25 mg daily (822)

**Comparator:** Placebo (841)

**1° endpoint:**
- **Death from all causes**

**Results:**
- Placebo vs. Spironolactone group (46% vs. 35%; RR: 0.70; 95% CI: 0.60–0.82; p<0.001)
- Trial stopped early due to favorable results at 24 mo.
- Reduction in death from cardiac causes and Hospitalization for cardiac causes (p<0.001)
- Improvement in NYHA class (p<0.001)
- No clinically important safety concerns for electrolytes. Gynecomastia/breast pain more frequent in the spironolactone group (p<0.001)

---

1° indicates primary; 2°, secondary; ACE, angiotensin-converting enzyme; ARB, angiotensin-receptor blockers; ACHD, adult congenital heart disease; BP, blood pressure; CAD, coronary artery disease; CI, confidence interval; CVD, cardiovascular disease; CV, cardiovascular; DM, diabetes mellitus, eGFR, estimated glomerular filtration rate; EMPHASIS, Eplerenone in Mild Patients Hospitalization and Survival Study in Heart Failure; HF, heart failure; MI, myocardial infarction; NNH, number needed to harm; NYHA, New York Heart Association; ONTARGET, The Ongoing Telmisartan Alone and in Combination With Ramipril Global Endpoint Trial; pts, patients; PVD, peripheral vascular disease; RCT, randomized controlled trial; RR, relative risk; SBP, systolic blood pressure; SUPPORT, Supplemental Benefit of ARB in Hypertensive Patients With Stable Heart Failure Using Olmesartan; TRANSCEND, the Telmisartan Randomised Assessment Study in ACE Intolerant Subjects With Cardiovascular Disease; and VHD, valvular heart disease.

Search Terms and Date: angiotensin-receptor blockers, ARBs, angiotensin-receptor blocker, ARB, angiotensin-receptor antagonists, angiotensin receptor antagonist, candesartan, irbesartan, losartan, telmisartan, valsartan, olmesartan, AND heart failure or congestive heart failure or CHF or HFrEF AND clinical trial, January 2016.

© 2016 American College of Cardiology Foundation and American Heart Association, Inc.
The ARB evidence table from the 2013 Heart Failure Guideline is included at the end of this document.

The ACE inhibitor evidence table from the 2013 Heart Failure Guideline is also included at the end of this document.

The Beta Blocker evidence table from the 2013 Heart Failure Guideline is included at the end of this document.

### Data Supplement 3. RCTs Comparing Pharmacological Treatment for of ARNI With ACE (Section 7.3.2.10)

| IMPRESS Rouleau et al. 2000 (8)      | Aim: Determine if inhibition of neutral endopeptidase and ACE with the vasopeptidase inhibitor omapatrilat is better than ACE inhibition alone with lisinopril | Inclusion criteria:  
  • Informed consent  
  • Age ≥18  
  • Stable (>3 mo) symptomatic HF (NYHA class II–IV HF)  
  • Decreased LVEF ≤40  
  • ≥4 wk dose of ACE inhibitors  
  • Seated SBP ≥90 mm Hg  
  Exclusion criteria:  
  • Uncontrolled hypertension  
  • Acute coronary events within 3 mo  
  • Revascularization within 3 mo  
  • Serum potassium <3.5 or >5.3 mmol/L  
  • Creatinine >221 mcmol/L  
  • Transaminases >2 upper limit of normal  
  • Leucocytes <3.0x10^9/L, neutrophils <1.5x10^9/L, or platelets <120x10^9/L  
  • Use of beta blockers <6 mo  
  • Calcium channel blockers for use other than AF  
  • Pts included in previous RCTs of omapatrilat | Intervention: Omapatrilat (289) target dose 40 mg daily  
  Comparator: Lisinopril (284) target dose 20 mg daily | 1° endpoint: Change in exercise duration from baseline to wk 12  
  1° endpoint: Combined risk of death or hospitalization for HF requiring IV treatment | 2° endpoint:  
  • No difference in combined endpoint of death and admission for worsening HF (p=0.52)  
  • Combined endpoint of death and comorbidity for worsening HF was better for omapatrilat HR: 0.52 (95% CI: 0.28–0.96; p=0.035)  
  • Angioedema occurred in no pts taking omapatrilat vs. 1 taking enalapril  
  Comments: Vasopeptidase inhibitor omapatrilat did not improve exercise tolerance compared with ACE inhibitor lisinopril |
| OVERTURE Packer et al. 2002 (9)      | Aim: Determine dual ACE and NEP inhibitors provides greater benefit in pts with HF than ACE inhibitors alone | Inclusion criteria:  
  • NYHA class II–IV HF due to non/ischemic cardiomyopathy for ≥2 mo, or  
  • LVEF ≤30% and hospitalized for HF within 12 mo  
  Exclusion criteria:  
  • Pts included in previous RCTs of omapatrilat | Intervention: Omapatrilat (2,886), target dose 40 mg daily achieved 82.5%  
  Comparator: Enalapril (2,884) target dose 10 | 1° endpoint: Combined risk of death or hospitalization for HF requiring IV treatment | 2° endpoint:  
  • Omapatrilat reduced risk of death and hospitalization for chronic HF HR: 0.89 (95% CI: 0.82–0.98; p=0.012). For this analysis, pts were treated with intensification of oral medications. |
### OCTAVE

**Kostis et al. 2004**

**Aim:** Compare safety and efficacy of dual ACE and NEP inhibitors to ACE inhibitors alone

**Study type:** Double blind RCT

**Size:** 25,302 pts

| SIGNIFY | Aim: Assess the mortality-morbidity benefits of ivabradine in pts with stable CAD without clinical HF |
| Study type: RCT | 19,102 |
| Exclusion criteria: Serum creatinine >200 mcmol/L, significant anemia, ALT or AST >3 times upper normal value, unstable CV condition, LVEF ≤40%, MI, coronary revascularization, stroke ≤3 mo. |
| Intervention: Ivabradine (n=9,550) Comparator: Placebo (n=9,552) | 1° endpoint: Composite of CV death and nonfatal MI |
| Results: No significant difference in incidence of 1° endpoint (HR: 1.08; 95% CI: 0.96–1.20; p=0.20), death from CV causes (HR: 1.10; 95% CI: 0.94–1.28; p=0.25), nonfatal MI (HR: 1.04; 95% CI: 0.90–1.21; p=0.60) and rate of death (HR: 1.06; 95% CI: 0.94–1.21; p=0.35) |
| 1° Safety endpoint: | Adverse Events: Increased bradycardia, AF, phosphenes and cardiac disorders. |
| Exclusion criteria: HF due to congenital heart disease or 1° severe valvular disease. MI within 2 mo, ventricular or AV pacing for ≥40% of the d, AF or flutter, symptomatic hypotension |
| The following treatments not allowed during study: diltiazem and verapamil (nondihydropyridine CCB) |
| class I antiarrhythmics |
| strong inhibitors of CYP450 3A4 |
| Hospitalization for worsening HF: ivabradine better. 16% vs 21%, HR: 0.74 (95% CI: 0.66–0.83; p<0.001) |
| Death from HF: ivabradine better. 3% vs. 5%; HF: 0.74 (0.58–0.94); p=0.014 |
| ivabradine better for all-cause hospitalization, HF hospitalization, CV hospitalization, and composite 2° endpoint |
| Analyzed as time to first event. Median follow-up of 22.9 mo |
| In subgroup analysis, effect limited to those with higher baseline heart rate (≥77 bpm) |
| Use of devices was low (CRT in 1% and ICD in 4%) |
| Mean age 61 y |
| When added to GDEM, including beta blocker at optimal dose, ivabradine reduced adverse events, driven largely by HF mortality or HF hospitalization |
| Adverse Effects: 1% withdrew due to bradycardia (p<0.001) |
| Phosphenes 3% (p<0.001) |
| Comparable across age groups |
| AF - ivabradine 9% vs. placebo 8% (p=0.012) |

Aim to find out whether the use of an ARB could reduce mortality and morbidity.

**CHARM-Overall**

- **Study Name**: CHARM-Overall
- **Study Type**: RCT - parallel, randomized, double-blind
- **Participants**: 9,222 patients
- **Main Endpoint**: All-cause mortality
- **Secondary Endpoints**: All-cause hospitalization
- **Duration**: 3.5 years

**Results**:
- **Mortality**: 15% in the candesartan group vs 17% in the placebo group
- **Hospitalization**: 38% in the candesartan group vs 42% in the placebo group

**Sub-studies**

- **CHARM-AFC (Candesartan in Heart Failure-Assessment of Reduction in Mortality and Morbidity)**
  - **Study Name**: CHARM-AFC
  - **Study Type**: RCT - parallel, randomized, double-blind
  - **Participants**: 2,123 patients
  - **Main Endpoint**: All-cause mortality
- **Results**: Candesartan reduced all-cause mortality by 25% compared to placebo.

- **CHARM-JAPAN**
  - **Study Name**: CHARM-JAPAN
  - **Study Type**: RCT - parallel, randomized, double-blind
  - **Participants**: 2,123 patients
  - **Main Endpoint**: All-cause mortality
- **Results**: Candesartan reduced all-cause mortality by 18% compared to placebo.

**PPM (Preserved Pumping Mechanism)**

**MERIT-HF**

- **Study Name**: MERIT-HF
- **Study Type**: RCT - multicenter, double-blind randomized placebo controlled trial (USA)
- **Participants**: 5,005 patients
- **Main Endpoint**: All-cause mortality
- **Secondary Endpoints**: All-cause hospitalization
- **Duration**: 1.3 years

**Results**:
- **Mortality**: 13.2% in the placebo group vs 11.0% in the treatment group
- **Hospitalization**: 13.4% in the placebo group vs 11.9% in the treatment group

**Background**

- **ACEI**: Angiotensin-converting-enzyme inhibitor
- **ARB**: Angiotensin receptor blockers
- **ASA**: Aspirin
- **CHF**: Congestive heart failure
- **CV**: Cardiovascular
- **DM**: Diabetes mellitus
- **EF**: Ejection fraction
- **HF**: Heart failure
- **HR**: Heart rate
- **IHD**: Ischemic heart disease
- **LV**: Left ventricle
- **NYHA**: New York Heart Association
- **SBP**: Systolic blood pressure
- **SCr**: Serum creatinine
- **TIA**: Transient ischemic attack
- **USA**: United States of America

**Diuretics**

- **Beta blockers**: Beta blockers reduce mortality and symptoms in heart failure patients.
- **Diuretics**: Diuretics are used to reduce fluid retention.
- **ACEI**: ACEI is used to reduce blood pressure and prevent heart failure.

**Conclusion**

- Candesartan and metoprolol significantly reduce the risk of mortality in heart failure patients.
COPERNICUS: Packer et al; (2002) 12999647
To compare the effects of carvedilol and metoprolol on clinical outcome in pts with HF
RCT—double blind
Dienetics (PO or IV) + ACE (or ARB); [Amododone allowed 17-18%]
228B; 1156; 1133
Ischemic 67%
Euvolumic NYHA class IV; LVEF <25%; No positive inotropes or vasodilators win 4 d
Pt requiring hospitalized intensive care; Use of positive inotropes or IV; vasodilators win 4 d
Coronary revascularization/MICVAD sign VT or VF win 2 mo; SBP < 85 mmHg; Heart rate < 60; Cr > 2.8 mg/dL
Severe Mean BP: 123/76; Mean HR: 63; Mean EF 20%
All-cause mortality
Combined risk of death or hospitalization—any reason; Combined risk of death or hospitalization—CV reason; Combined risk of death or hospitalization—HF reason; PT global assessment
19.7% placebo [24.0% in pts with recent or recurrent cardiac decompensations]
18.5% in placebo group
11.4% in carvedilol group
10.4 mo
Treating 1000 pt for 1 y led to savings of 70 premature deaths p=0.0014

SENIORS, Flather et al; (2005) 12647700
To assess the effects of the beta blocker nebivolol in pts >70 y regardless of EF
RCT
Dienetics + ACEI (+aldosterone antagonist in 29%)
212B; 1067; 1001
Prior h/o CAD in 69%
Age >70 CHF with 1 of the following: hospitalization with CHF win a year or EF <35% win the past 6 mo
New HF therapy win 6 wk or change in drug therapy win 2 wk
Contraindication to beta blockers, current use of beta blockers, significant renal dysfunction
CVA win 3 mo.
Mild to severe Mean BP: 139/81; Mean EF: 79; Mean EF >36% (1/3 with EF >35%);
Composite of all-cause mortality or CV hospital admission
All-cause mortality
Composite of all-cause mortality or all-cause hospital admissions
All cause hospital admissions CV hospital admissions
CV mortality
Composite of CV mortality or CV hospital admissions
NYHA class assessment; 6 MWT

N/A
1.75 y
Absolute risk reduction 4.2%; 24 pts would need to be treated for 21 mo to avoid one event
RR: 0.86; 95% CI: 0.74-0.99; p=0.039

A Trial of the Beta-Blocker Bucindolol in Pt with Advanced Chronic HF: The Beta-Blocker Evaluation of Survival Trial Investigators 11986364
To determine whether bucindolol hydrochloride, a nonselective beta-adrenergic blocker and mild vasodilator, would reduce the rate of death from any cause among pt with advanced HF and to assess its effect in various subgroups defined by ethnic background and demographic criteria — specifically women and members of minority groups
RCT
ACEIs (if tolerated) [91% ACE]; 7% ARB); for at least 1 mo Before the publication of the results of the DIG trial, 12 digoxin therapies were required, but thereafter its use became discretionary [DIG 94%]
270B; 1354; 1354
Ischemic 59%
NYHA class III or IV HF LVEF <35% >18 y
Reversible cause of HF—present Candidates for heart transplantation Cardiac revascularization procedure within the previous 60 d UA Heart rate <50 bpm, SBP <100 mmHg
Decompensated HF.
NYHA II or IV (92% class III) EF 29%; HR 62; BP 117/71; AF 12%
Death from any cause
Death from CV causes (death due to pump failure or an ischemic event or sudden death) Hospitalization for any reason Hospitalization because of HF
Composite of death or heart transplantation LVEF <3 and 12 mo MI; QoL; and any change in the need for concomitant therapy
For pt in NYHA functional class III, the annual mortality rate was 16% in the placebo group; For pt with NYHA class IV, the annual mortality rate in the placebo group was 28%
Overall: annual mortality of 17% in placebo group and 15% in the bucindolol group
N/A

4.8 y
All-cause mortality 34% carvedilol and 40% metoprolol (HR: 0.83; 95% CI 0.74-0.93; p=0.0017)
Sufficient data do not currently exist to establish the optimum order of initiating chronic HF therapy (ACEI vs. beta blocker). This was the objective of the CIBIS III trial—it compared the effect on mortality and hospitalization of initial monotherapy with either bisoprolol or enalapril for 6 mo, followed by their combination for 6 to 24 mo.

**Diuretics**
- 84%; Digoxin 32%

**CAD 62%**
- >65 y, NYHA class II or III, and LVEF <35% (by echo within the 3 mo)

**Treatment with an ACEI, an ARB, or a beta blocker for >7 d during the 3 mo before randomization**
- Heart rate at rest <60 bpm without a functioning pacemaker
- Supine SBP <100 mm Hg at rest
- SCr≥220 mmol/L
- AV block>1° without a functioning pacemaker
- Obstructive lung disease contraindicating bisoprolol treatment

**NYHA II or III, mild to moderate CHF**
- LVEF 29%; Heart rate 79; SBP 134

**The primary endpoint was time-to-the-first-event of combined all-cause mortality or all-cause hospitalization**

**Combined endpoint at the end of the monotherapy phase and the individual components of the primary endpoint, at study end and at the end of the monotherapy phase.**
- CV death
- CV hospitalization

| N/A | 1.22±0.42 y (maximum of 2.10 y). |
| N/A | In the ITT sample, 178 pt (35.2%) with a primary endpoint in the bisoprolol-1st group, and 186 (36.8%) in the enalapril-1st group (absolute difference -1.6%; 95% CI: -7.6 to 4.4%; HR: 0.94; 95% CI: 0.77–1.16; noninferiority for bisoprolol-first versus enalapril-1st treatment, p=0.019) |
